

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

# AUTOMOTIVE INDUSTRIES

## The AUTOMOBILE

Where

*Is the Largest Group?  
of Automobile Buyers?*

Model "K." Lycoming Motor

The group which constitutes the biggest market for automobiles is to be found among the more than 3,000,000 people whose incomes range between \$2,000 and \$10,000.

Obviously, price is an important factor of choice with the buyers in this group, as is evident from the chart which shows 90% of all cars sold are "Fours," which type predominates among the low and moderate price cars.

In this big market the Lycoming Motor has a unique place as an equipment asset for both car manufacturer and car owner. A simple, dependable "Four," made in one type and model only, it provides a power plant capable of doing anything that any motor can do and yet leaves a wider margin for balancing body and chassis value to enhance riding comfort and economy, than could be secured under the added expense of more cylinders.

*A booklet describes the Lycoming Motor. Write for it.*

### Number of Cars Sold - 1920

\*Exclusive of Fords.

**Lycoming Motors Corporation**

Williamsport, Pa.

## FEDERAL BEARINGS

### UNIFORMITY

The Babbitt lining in every Federal Bearing shows the same tough, fine-grained, homogeneous structure because every Bearing is chilled immediately after it is lined.

### SOLIDITY

Every Federal Bearing is guaranteed absolutely free from porosity, because the process of manufacturing makes it impossible for the Babbitt to contain air while cooling.

### 100% BOND

Unlike all other methods of manufacturing Bearings, the Babbitt lining and Bronze Back of every Federal Bearing is Bonded UNDER PRESSURE while the adhering alloy is at a constant temperature.

### EXCELLENCE

Every Federal Bearing is manufactured from the highest grade materials, machined accurately and subjected to the most rigid inspection, because "FEDERAL, DETROIT" must be stamped on the back.

EVERY FEDERAL BEARING IS LINED BY  
**CENTRIFUGAL FORCE**

(Process protected by patents)

**FEDERAL BEARING & BUSHING CORPORATION**  
BABBITT-LINED BRONZE-BACK BEARINGS - BRONZE BUSHINGS - BRONZE CASTINGS  
DETROIT - MICHIGAN

**INDEX**  
**TO**  
**VOLUME XLV**  
(July 7 to December 29, 1921)  
**OF**  
**Automotive Industries**

Here is an accurate guide to the authoritative articles and reference data which have appeared in AUTOMOTIVE INDUSTRIES during the last six months. The publication of this index is in line with our constant efforts to make this publication of maximum service to the entire automotive industry.

## The AUTOMOBILE

# INDEX TO VOLUME XLV

ISSUES OF JULY 7, 1921, TO  
DECEMBER 29, 1921, INCLUSIVE

July 7.....	1- 50	Air Mail—		American Turn-Auto Co.—obtains patent rights.....	1199
July 14.....	51- 100	German air-mail post office in Berlin...	383	Anderson Motor Car Co.—cuts prices...	644
July 21.....	101- 150	Restoration of airplane mail service between St. Louis and Chicago.....	1192	Anglo-Amer. Motors, Ltd.—settles on plant site.....	942
July 28.....	151- 200	Airplanes—		Angus Sanderson, no cash and creditors...	395
Aug. 4.....	201- 250	Curtiss Navy Racer described (ills.)...	1015	Ansted motor infringes Brush patents...	737
Aug. 11.....	251- 300	Fokker monoplane described (ills.)...	1113	Apperson Bros. Auto Co.—reduces cars...	97
Aug. 18.....	301- 350	French sporting airplane described (ills.)...	707	Branch replaces distributor in St. Louis	1191
Aug. 25.....	351- 400	Lloré & Oliver armored biplane (French) (ills.)...	359	Schedule about equal to 1915 or 1916...	986
Sept. 1.....	401- 450	Nieuport latest product described (ills.)...	658	Apple, V. C.—Poor batteries an economic waste	431
Sept. 8.....	451- 500	Roma, Italian dirigible (ills.)...	272	Argentine tractor trials—results of....	403
Sept. 15.....	501- 550	Air Reduction Co.—		Argentine automotive market.....	877
Sept. 22.....	551- 600	Neon filled tubes for ignition tests (ills.)...	603	Show successful	1041
Sept. 29.....	601- 650	Akron—Overland Tire Co. injunction halts use of "Overland" name for tires	90	Truck possibilities in Argentine.....	1098
Oct. 6.....	651- 700	Alaska—tractors in use in.....	581	Armature—Production methods in (ills.)	318
Oct. 13.....	701- 750	Alcohol—fuel problem in England.....	410	Armleder Co. brings out a new model...	889
Oct. 20.....	751- 800	Alena Steam Products—to make engine only	40	Army Ordnance Assn. convention gives demonstration	745
Oct. 27.....	801- 850	Alliment chart (ills.)...	614	Army surplus materials—distribution chart of, by States.....	81
Nov. 3.....	851- 900	Allen Motor Co.—receivers ask permission to sell.....	738	Bill to ban truck re-imports revised...	289
Nov. 10.....	901- 950	Prices reduced.....	694	Government sales closed for the time...	800
Nov. 17.....	951-1000	Allied Motor Commerce, Inc., organized in Indiana	793	Government will buy few motor vehicles	1147
Nov. 24.....	1001-1050	Plans transport school.....	993	Re-imported trucks measure important to industry	337
Dec. 1.....	1051-1100	Allis-Chalmers Mfg. Co.—gets \$200,000 Ford order	438	Two measures cover truck dumping evil	36
Dec. 8.....	1101-1150	Aluminum—		ARO reduces price of tractor.....	896
Dec. 15.....	1151-1200	Aluminum from the engineer's viewpoint	1130	Arrow Pump Co.—new design of circulating pump (ills.)...	174
Dec. 22.....	1201-1250	Aluminum pistons.....	229	Associated Machinery Corp.—formed...	998
Dec. 29.....	1251-1300	French Soc. "Aluminum Week".....	515	Associated Motor Industries take Jackson Motors	836
		German trials of aluminum pistons...	904	26 companies included in automotive merger	1145
		Metallic beryllium added to aluminum	612	Associated Technical Soc.—Plan to merge Detroit engineering societies...	492
		New aluminum alloy developed.....	1233	Athol Mfg. Co. denies unfairness in mfg.	636
		Production of aluminum pistons (ills.)	722	Atlas "Merchants' Dispatch"—Atlas reduced	447
		Protection of aluminum from corrosion	576	Atlas price down.....	847
		Relative value of aluminum and steel as body panel material.....	173	Atterbury Motor Car Co. has new prices	649
		Testing aluminum castings.....	431	Atwater Mfg. closes down.....	843
		Use of wrought aluminum alloys in auto construction	862	Aultman & Taylor reduces price of tractor	896
		Amer. Bosch Magneto Corp.—adds battery ignition system	100	Austin Motor Co. drawing of transmission	609
		Producing a battery ignition system (ills.)	209	Australia—	
		Amer. Com. Car Co.—"Wolverine" truck cut	49	Australia lowers duty on tractors.....	946
		Amer. Electrochemical Soc.—research work on electroplating.....	420	Automobile shortage is seen in Australia	846
		Amer. Gear Mfrs.—papers read at convention	755	Imports improve.....	900
		Standardizing differential gears.....	923	Austria produces many automobiles...	831
		American Mfrs. Export Assn.—annual convention	730	Austrian-Daimler car desc.....	1245
		Amer. Metal Products Co.—to open new metal foundry	450	Autocar Plants—Effective labor policy...	168
		Amer. Motors Corp.—receiver appointed for	495	Autocar reduces prices.....	1196
		Amer. Petroleum Institute—Co-operation urged at meeting.....	1128	Automatic Steam Carburetor Co. pays damages	892
		Amer. Road Builders Assn.—officers elected	1041	Auto. Financing Credit Men's Ass'n convention	638
		Amer.—Southern Motors Corp.—introduce "Vaughn" car	539	Automobile Sundries Co.—firm bankrupt	540
		American Tire Corp. reduce prices.....	1046	Automotive Body Corp.—formed.....	1242
				Automotive Corp.—roadster to be built...	1039
				Automotive Equipment Assn. plans laboratory	1138
				Sales promotion movement of the A. E. A.	1180
				Automotive Service Assoc. of N. Y. and Bklyn. plan campaign for winter repair work	639

Automotive Supply Co. organized to take over Root firm.....	241	Demonstration at Fargo shows tractors more economical.....	126	Bourdon, M. W.—	
Automotive Wood Wheel Mfg. Assn. latest group in M. A. M. A.....	597	1922 cornbelt sales limited but better business is ahead.....	1276	British Daimler to produce new 4-cylinder chassis.....	458
Avery Engineering Co.—air operated jack (ills.).....	933	N. I. V. A. discusses difficulties of farm implement industry.....	751	British tractor trials develop interesting engineering features (ills.).....	817
Aviation—		Prices reduced.....	694	Cowey spring suspension desc. (ills.).....	853
A. E. F. Air Service circular report ready.....	311	Belflex fabric spring shackle.....	977	Crossley 4-cylinder model, desc. (ills.).....	355
Acosta wins Pulitzer Trophy Race.....	939	Belgium, needs garage equipment.....	141	Design variations feature British light cars (ills.).....	1108
Aeronautical Chamber of Commerce formed.....	1296	Car imports of Belgium.....	480	Developments in bodywork on British cars (ills.).....	1057
Aeronautical committee makes recommendations.....	1197	Engineers want tariff changed.....	1111	Engineering features of British cars at London show.....	1006
Aeronautical Safety Code discussed.....	115	Bell, G. B., named chief of vehicle division.....	488	Engineering features of British truck models (ills.).....	958
Aircraft Yearbook, 1921, ready.....	326	South African tractor market demands study, Pt. 1.....	1228	Engineering features of popular Rover car.....	404
Airplane superchargers (Technical—Note No. 48).....		South African tractor market demands study, Pt. 2.....	1279	Multiplicity of models feature British motorcycle show (ills.).....	1264
Air routes across the Sahara.....	264	Bills, see Laws—		New British chassis (Leyland) incorporates many novelties (ills.).....	6
Brief report on civil aviation in Great Britain.....	702	Bell Trucks Sales Corp., to handle Bell trucks.....	300, 538	New model light cars planned by British makers.....	309
British air ministry to analyze engine development.....	720	Belsize Motor Co., defers payment of dividend.....	591	New small cars feature British automobile show (ills.).....	901
Chinese airplane gives excellent performance.....	443	Benz (German show).....	758	Weather protection on British open cars (ills.).....	1163
Civilian aviation gained 20 per cent in 1921.....	1238	Benz Works buy Kumpfer patents.....	1300	Wind screens design for back seat (ills.).....	260
Civil aviation in Switzerland given aid.....	1263	4 & 6 cylinder engines desc. (ills.).....	56	Bournville Rotary Valve Motor Co., new Rotarian to make transcontinental run.....	148
Commercial aviation abroad.....	1229	Bergougnan, solid rubber tires.....	225	New Bournville rotary valve engine desc. (ills.).....	1065
Developing a ground organization for civil aviation, Part 1.....	573	Berry, O. C. (Prof.) "Some factors affecting carburetor design and operation".....	357	Bowen Products Corp., a pressure lubricating system, grease gun.....	107
Part 2.....	622	Berson, photo of triplane.....	1157	Bowser, S. F., absorbs Richardson-Phoenix.....	842
England stops airship development.....	314	Bethlehem Motors Corp., to be sold.....	1048	Bradley, W. F.—	
Experiments with reversible propeller at McCook Field.....	613	Bethlehem Rolled Steel Wheel, description of, (ills.).....	503	Design features brought into relief by Grand Prix (ills.).....	303
Fair leads (detachable), for aircraft (ills.).....	7	Birmingham Motors, formed in N. Y.....	442	Developing a ground organization for civil aviation, Pt. 1.....	572
Foreign commercial flying needs government aid.....	779	Black & Decker arranges time payment sales plan.....	692	Part II.....	622
Forgings and castings to be sold.....	1040	Blanchard, Harold F., neglect in finishing a car.....	1082	European engineering trends shown at Paris show (ills.).....	804
France to give prize for best commercial air motor.....	696	Bleriot, photo of airplane.....	1157	First German show in ten years (ills.).....	753
French aviation firms are now consolidated.....	92	Bob (German show).....	758	French makers turn to medium-priced cars.....	430
Goodyear making navy balloonettes.....	1238	Bodies, design—		Germany holds first post-war show.....	637
High altitude aircraft of the future.....	418	Body design at the automobile salon (ills.).....	1054	Ground organization for civil aviation (ills.).....	622
Tacuzzi plans destruction blamed on gas tanks.....	196	Body design at the N. Y. salon (ills.).....	1115	Trend to light cars in Paris show.....	701
Metal airplane construction.....	1220	Body dimensions of British cars (ills.).....	1058	Braender Rubber & Tire Co. has reorganization plan.....	241
New theory of the slotted wing.....	731	Closed body production costs minimized in Essex coach (ills.).....	956	Receivership lifted.....	1093
R-38—official report on disaster.....	981	Combination roof construction for enclosed bodies.....	14	Brakes—	
Record of civilian aviators in 6 months (by miles).....	191	Convenience in car bodies.....	783	Air-operated brakes.....	31
U. S. gives Goodyear aircraft contract.....	90	Demand for low priced closed car.....	1001	Automatic brake regulation to prevent wheel locking (ills.).....	964
U. S. Navy's hangar at Lakehurst, N. J., desc.....	130	Demountable body carriage (ills.).....	778	Bonner's brake lining data.....	160
Various possibilities in airplane flying controls.....	569	Developments in bodywork on British cars (ills.).....	1057	Crane's band brake desc. (ills.).....	1261
ZR-2 is destroyed; loss of life heavy.....	393	Finish of closed car interiors.....	1231	More accessible emergency brakes.....	380
Axes—		Limousine Top Co., making practical sedan body.....	391	Shuler front wheel brake (ills.).....	79
Clark Model B-21 bevel gear axle.....	483	Offer awards for designs at body builders exhibit.....	1297	Uniform braking on four wheels.....	431
Production of rear axle truck forgings (ills.).....	619	Perrin Co.'s demountable body carriage for truck use (ills.).....	60	Brake Lining Tests, at Bureau of Standards.....	108
Russel internal gear truck axle desc. (ills.).....	921	Plywood as body material (ills.).....	414	Brazil, distribution policy for the market.....	1080
Unsprung weight axles and spring action.....	980	Progressive production methods applied to body building.....	73	Breguet, photo of airplane.....	1157
		Relative value of aluminum & steel as body panel materials.....	173	Brennabor (German show).....	758
B		Semi-racing roadster body (ills.).....	1155	Brewster, photo of a berline.....	1116
B. M. W. engine (German show).....	763	Some features of body-design.....	381	Photo of interior of cabriolet.....	1119
B. S. A.—photo of chassis.....	802	Weather protection on British open cars (ills.).....	1163	Briscoe Motor Corp. changed to Earl Motors.....	687
Specifications of B. S. A. light car.....	1110	Body Panels, a new service problem, of patching body panels.....	321	British Dunlop Tyre Co., innovations of British Electrical & Allied Industries Research Assn., progress report.....	533
Bachman, B. B. & Ripplingille, E. V. Relation between factory service and engineering depts.: Pt. I, Bachman; Pt. II, Ripplingille.....	323	Bollstrom Motors, has receiver.....	388	British Engineering Standards Assoc. form committees for standardization.....	621
Bakelite Co., wins ruling in suit over patents.....	291	Ruggles Motor Truck Co., takes Bollstrom.....	1190	British Ensign Motors in hands of creditors.....	637
Banjo-type rear axle truck forgings (ills.).....	619	Bolt, self-adjusting connecting rod (ills.).....	1014	Briton car, photo of gearshift lever.....	1009
Bank subjects—		Book Reviews—		Brooking Mfg. Co., uniflow manifold (ills.).....	925
Bank relations department will aid Lexington dealers.....	1287	Aircraft Handbook, second edition.....	957	Brown, Geo. M., fuel problem as a carburetor problem.....	680
Federal Reserve Bank of N. Y. reduces discount.....	143	Aircraft Yearbook, 1921.....	326	Brush charges Ansted motor infringes patents.....	737
Must endorse notes of financing firms.....	544	"Aircraft-engine development," by Deschamps & others.....	533	"Brute" trailer (ills.).....	526
National Assn. of Automotive Bankers formed.....	742	Aircraft Year-book ready.....	283	Buckeye Mfg. Co., receiver named.....	945
Barco Battery Co.—Changes methods of distribution.....	1187	Airplane super-chargers, from "Technical Note No. 48".....	23	Buda Co. incorporates Automotive Parts Corp.....	1244
Barduff, Ltd., one-way spring damper.....	210	"America's Power Resources".....	674	Bugatti car, spring-mounting on.....	103
Barley Motor Car Co. has added new top.....	839	"Auto Gear Information Service".....	231	Crossley Motors, Ltd., to produce Bugatti.....	1096
Bartlett, E. J., "Relative value of aluminum and steel as body material".....	173	Automobile repairman's helper.....	681	High speed of car shown at Bugatti race.....	643
Bartlett, G. M., development of the roller chain drive.....	363	Book containing petroleum laws.....	733	Buick Motor Co., new Buick "4" desc. (ills.).....	255
Bassick Mfg. Co., Rimco suit is settled amicably.....	488	Circular No. 100 on "Nickel" by Bureau of Standards.....	356	Price cut.....	1287
Battery—Ray Battery Co.'s production methods (ills.).....	18	Economic aspects of Great Lakes-St. Lawrence channel.....	626	New "Four" will be marketed for \$975 (ills.).....	194, 195
Battery life, by Fraser.....	333	Eliminating waste in industry.....	1183	Shipments for June.....	87
Bosch producing a battery ignition system.....	209	G. M. Co.'s booklet on Corp.'s magnitude.....	195	Shipments of Buick cars during Aug. first half.....	388
The life of storage batteries.....	280	German auto engineering handbook.....	475	Bulgaria, electric cars.....	1025
Poor batteries an economic waste.....	431	Gill Mfg. Co., number & size of piston rings.....	963	Bull-Madison Motors Corp., assets go to bondholders.....	545
Rubber compound battery box (ills.).....	864	Oscillograph measurements of values of current & voltage in battery circuit of automobiles.....	1270	Bondholders' claims supersede claims of general creditors.....	740
Tests of new Ray battery.....	446	Report of A. E. F. air-service.....	311	Burford truck, photo of front wheel brake.....	910
Baumgart, C. A., Motorcycles on the farm.....	1230	Time study and job analysis.....	1033	Burt engine introduced here.....	1040
Reardmore, photo of car.....	903	"Trade of the New Countries of Southeast Europe".....	397	Buses—	
Bearings, running loads.....	667	"White Metal Bearing Alloys at Elevated Temperatures".....	356	Bus problem discussed at Electric R. R. convention.....	726
Engine bearing with radiating flanges.....	1121	Bosch Magneto Co. (Robert) Inc., Helms heads German Co.....	487	Buses carry 15,000 monthly in Toledo.....	1058
Beecroft, David—		Des. of Robert Bosch electrical equipment.....	671		
Auto business survives adversity in North Dakota.....	51	Boston "Safety Week" follows big convention.....	194		

Dimension for English buses.....	1263
English char-a-bancs & motor buses.....	1281
"Mack" bus chassis (ills.).....	503
Bus, Mack desc. (ills.).....	24
Motor bus field as market for trucks.....	627
Motor bus successful in street railway use.....	407
Motor bus transportation in British Isles (ills.).....	827
Municipal transportation improvements.....	969
Railroad replaces trains with buses.....	1000
Requires financial aid of bus patrons.....	841
Test proves bus more economical than rail.....	795
Three Mack buses to be used on N. Y., N. H. & H. R. R.....	794
Business car desc. (ills.).....	917
Business Publishers Assoc. gives course of Industrial Journalism.....	630

## C

Cadenhead Auto Rim Co., nears early production.....	47
Cadillac Motor Co., model 61 desc. (ills.).....	555
Increases force.....	340
Production.....	542
Price cut.....	1287
Caledon truck, photos of chassis & engine.....	960
Gear shift coupling (drawings).....	962
Cadwell, E. D., incorporates as Monarch tractors.....	289
Calorimeter, for determining the heat of ignition sparks (ills.).....	523
Calthorpe light car specifications.....	1110
Cameron Motors Corp., takes over Sandusky tractor.....	92, 337, 391, 494
Canada, motor statistics.....	94
American factories in Canada.....	892
Canadian farmers and automobiles.....	1027
Canada will issue trade certificates.....	488
Description of Canadian National exhibition.....	459
Figures given for potential market.....	638
Canadian Auto Corp., to make new "Mercury" 6 car.....	250
Canadian Gary Co., formed.....	347
Canadian Tool Salvage Co., trade grows.....	436
Car owner is boss of automobile industry.....	1021
Cars, see small and light cars—	
Car Desc.—	
Austrian-Daimler car desc.....	1245
Bean model (Eng.) appears in Japan.....	496
British Daimler 4-cylinder chassis (ills.).....	458
Buick 4 model fully desc. (ills.).....	255
Cadillac model 61 desc. (ills.).....	555
Chevrolet "four-ninety" model desc. (ills.).....	559
Cole eight desc. (ills.).....	1004
Crossley 5-passenger car with 4-cylinder engine.....	355
Detroit electric coupe desc. (ills.).....	1114
Duesenberg desc. (ills.).....	854
Durant car, new model's technical features desc.....	306
Earl car desc. (ills.).....	811
Eco car, for Australian use (ills.).....	409
Essex coach desc. (ills.).....	956
French makers bring out medium priced cars.....	430
Handley-Knight 1922 model desc. (ills.).....	1112
Haynes 1922 model "75" desc. (ills.).....	764
Hudson, refinements in control characterize new (ills.).....	604
Itala car desc. (ills.).....	1205
New Jordan model desc. (ills.).....	654
La Traction Aerienne (French "Wind Wagon") (ills.).....	539
"Midget" car appears on Japanese roads.....	292
New model light cars planned by British makers.....	309
Premier 6-D desc. (ills.).....	1262
Protos, a German car des. (ills.).....	703
Richelieu car desc.....	1122
Richenbacher Six desc. (ills.).....	1258
Robertson Co. to make special car for pulling on mountains, etc.....	142
Rover (Eng.) 8 hp. air-cooled run-about car (ills.).....	404
Royal Six desc.....	939
Rumpler desc. (ills.).....	812
Stevens-Duryea Six desc. (ills.).....	1061
Wills-St. Claire desc. (ills.).....	912
Car Operation, power required for.....	131
Carbureters—	
Air bleed in carbureter compensation (ills.).....	968
Holley plain tube carbureter, desc. (ills.).....	259
Packard single six carbureter, desc. (ills.).....	358
Some factors affecting carbureter design and operation (from Berry's tests at Purdue Univ.).....	357
Trials of German carbureters for using non-volatile fuels.....	4
Carter Motor Car Co., incorporated.....	736
Case, Boyd & Co., plan toll highway.....	386
Case cars, prices down.....	49
Case hardening.....	822
Case, J. L., Plow Works Co., receive medal from Portugal.....	848
Case car reduced.....	1046

Castings — Centrifugal castings desc. (ills.).....	109
Casting an aluminum head on a steel cylinder.....	474
Malleable castings discussed by S. A. E.....	888
Requirements for piston castings.....	826
The specifications & testings of castings.....	217
Technical data on cast iron properties.....	406
Cast-iron research ass'n. formed in Gt. Britain.....	673
Centaur Tractor Co., reduces price of tractor.....	896
Central Freight Assn., see reduced F. O. B. rates.....	200
Central Steel Co. formed.....	686
Chain Belt Co., have big demand for castings.....	1138
Chain drive, application & mfg. of silent chain (ills.).....	773
Development of the roller chain drive.....	363
Chalmers Motor Car Co., price reduction.....	896
Champion Ignition Co., desc. of speedometer (ills.).....	1053
British Co. joins with Champion ignition.....	1190
Champion Motors Corp., cuts.....	49
Champion Porcelain Co., organized.....	541
Chart, alignment chart (ills.).....	614
Chase, Herbert, Production of truck banjo-type rear axle forgings (ills.).....	619
Copper tube extrusion and the mfg. of radiator cores (ills.).....	870
Executives should foster use of standards.....	1101
Mack bus chassis desc. (ills.).....	503
Mack chassis now adapted for use on rails (ills.).....	918
Navy racer which won the Pulitzer trophy (ills.).....	1015
Petroleum research needed, meeting shows.....	1154
Stevens-Duryea six desc. (ills.).....	1061
Why our fuel supply must be conserved.....	251
Wright Aeronautical Corp.'s laboratory for air-engine tests.....	520

NO. 1

## What the New Tariff Bill Means to the Automotive Industry

Authority for Negotiation of Bargaining Tariff Treaties Opens Way for Better Export Conditions and Special Clause in Automotive Section Recognizes Industry as Leader in Foreign Trade. Aluminum Figure a Disappointment.

By Clyde Jennings

**T**HE clauses in the new tariff bill which expressly permit the President to negotiate bargaining tariff treaties promise more for the automotive exporter than he has ever been able to see in any previous legislation of this kind. The fact that one of these clauses is in the automotive section of the bill sets aside all doubt as to whether the members of Congress engaged in drafting this bill had a proper appreciation of the importance of the automotive vehicle as export merchandise.

The bargaining tariff feature will enable the seller of American goods to capitalize the import consumption of this country to lower the price of his wares in a foreign country. We have, in this country, a very large consumption ability for Jamaica bananas. Jamaica has a relative consumption possibility for American automotive vehicles. If Jamaica wants cheap automobiles, then they must permit us to have cheap bananas.

The working of this sort of a tariff situation is illustrated differently in connection with the treaty clause in the automotive section of the bill. The bill sets the import duty at 25 per cent American valuation for foreign cars. France to-day imposes a duty at 45 per cent on American cars. The President is authorized to negotiate a treaty whereby each country will admit the other's automotive vehicles on the

25 per cent basis. In case the other country refuses, the President can increase the import duty on vehicles from that country to a maximum of 50 per cent ad valorem.

The proposal for a reduction of the American import duty from the present 45 per cent to 30 per cent was made by the National Automobile Chamber of Commerce some months ago and created much surprise in Congress, where practically all industries were asking for more protection. Indeed, some congressmen advised the automotive manufacturers that they were making a mistake, that Europe with its cheap labor would be flooding this country with cheap motor cars. The American manufacturers, however, assured Congress that they were unafraid and were ready to meet competition in this country or any part of the world, and with a lower tariff they believed that they would gain more than they would lose.

So the reduction has been written into the bill, the figure being 5 per cent lower than that the industry asked. This, however, is equalized by the change of valuation basis. Formerly the tariff was imposed on the European valuation. Under the present bill it is imposed on the American valuation, which includes freight, insurance and various other expenses which go to make the cost to the sales agent in this country. The result is that the 25 per cent in the Fordney bill

is equal to practically 31 per cent under the law it is proposed that this bill will succeed.

The National Automobile Chamber of Commerce has prepared the following summary of the points in the new tariff bill:

1. The following points of particular interest to the automotive industry are contained in the first committee print of the tariff bill, made public by the Ways and Means Committee of the House, Wednesday.

2. The import duty on all automobiles, bodies, chassis and parts, not including tires, is decreased to 25% of American valuation. The duty under the Underwood Act was based on the lower foreign valuation. When a foreign manufacturing country imposes a higher duty for such imports, duties here may be similarly increased, not to exceed 50% ad valorem.

3. Under special provisions, the President is empowered and directed to meet any import duties levied by other countries which he may deem to be reciprocally unequal and unreasonable, by suspending similar schedules here and levying such additional duties as he may deem necessary to equalize such rates.

4. The duty on aluminum, aluminum scrap, and alloys of any kind in which aluminum is the component part of chief value, is increased from 2 cents per pound to 5 cents. Request of the aluminum producer was for 7 cent tariff.

5. Crude oil and fuel oil are listed for duty of 35 and 25 cents per barrel respectively.

6. Motor vehicles sold for war purposes on which the U. S. internal taxes were not paid, would be subject to a duty equal to those taxes upon reimportation into U. S.

7. Assurance has been given that a resolution will shortly be introduced in the House which may provide duty as high as 300% on reimported war material of American manufacture; such procedure would afford protection at earlier date than tariff.

The disappointment in the bill, as set forth in this statement, is chiefly contained in paragraph 4, regarding the duty on aluminum. The automotive industry opposed by argument and otherwise the increase of this duty, but they did not press the point as strongly as some other industries. The automotive industry has at all times taken the position that it is necessary to have some taxes that will contribute toward the support of the Government,

and aluminum is one of these.

The oil tariff, as set forth in paragraph 5, is higher than the automotive industry would like to have it. The same reasoning that applies in the previous paragraph applies here, with the additional circumstances that the oil industry is an industry of its own and that the various currents of influence in this reach very deeply into politics and finance, so that the automotive industry cannot object to duties that are satisfactory to those chiefly concerned. It was thought that if a tariff was left on oil there might be a less disposition to put domestic taxes on motor fuel.

Paragraphs 6 and 7 refer to the reimportation of automotive vehicles and other materials sold abroad for war purposes and many of which are now being returned to this country by speculators who have purchased them abroad.

In the tariff bill is a clause which would impose upon these goods all of the domestic taxes which they escaped because of being sold for war purposes. This would remove a part of the present unfair competition conditions. It would mean that before a vehicle could be sold as a used vehicle the tax equal to the sales tax on a new vehicle must be paid.

The Graham resolution, which is referred to in paragraph 7, would practically prohibit the return of this material to this country. It would provide an import duty as high as 300 per cent of this merchandise. This resolution is independent of the regular tariff bill and, from present prospects, seems very likely to be passed by both houses.

The favorable action upon the requests of the automotive industry by the congressional committees engaged in the drafting of the tariff would appear to be a subject for congratulation to those who represented the industry before these committees. The chief spokesmen were George M. Graham and C. C. Hanch. Their appearance before the committees was staged by Alfred Reeves of the National Automobile Chamber of Commerce and his staff. It has been the subject of comment in Washington that the automotive industry has made an excellent impression there by its give-and-take attitude and the ingenuity of its appeal.

## Visual Inspection of Combustion

**I**N the development of the internal-combustion engine visual observation of the combustion has played a minor role. To be sure, early investigators did provide apparatus that permitted them to look in the cylinder while the engine was operating, but little has been done in this direction with engines operating at the high speeds of the present day automobile types. Interest has centered in what an engine could do rather than how it did it.

At the present time the cry for fuel conservation has reawakened interest in the nature of the combustion in the cylinder. Glass induction systems have disclosed how unsatisfactorily the fuel has been prepared for combustion. Analyses of the exhaust gases have shown how incompletely the charge has been burned.

This has been accomplished in connection with the study of combustion in the one-cylinder Liberty engine at the Bureau of Standards in the following manner: A spark-plug shell has been adapted to receive a circular section of glass intended to serve as a window in the cylinder. This assembly can be used in place of either spark-plug in the ordinary aviation cylinder, but in this instance an additional boss has been welded to the cylinder in order that conditions might be observed with both plugs firing. Its use was satisfactory in that changes in flame color due to changes in air-fuel ratio were easily discovered. Since

the entire combustion stroke is completed in one-sixteenth of a second at an engine speed of 1800 r.p.m., it is possible to see only the predominant color by this means.

To make it possible to observe the combustion in its various stages a stroboscopic disk was added. Its purpose is to permit the combustion to be observed only a small portion of the stroke. Since there is one power stroke for every two revolutions of the crankshaft, this disk is driven at one-half crankshaft speed. The flame is observed through a slot in the disk, the length of the slot governing the length of the portion of the stroke studied. Provision is made for altering the angular relation of this slot to the crankshaft so that any interval of the cycle and, hence, any stage of combustion can be studied.

Observations made possible by this apparatus have proved of considerable value in research work of the nature described by permitting observations of the duration of luminous flame during the power stroke, the characteristic differences in color and brightness at different phases of combustion and their variation with changes in ignition timing, mixture ratio, compression pressure, etc. One observes, for instance, excessively bright flashes of flame of extremely short duration accompanying the phenomenon known as fuel knock or detonation. The cause for this phenomenon is of course not revealed.

# Kansas Adopts Weight as Motor Vehicle License Basis

Cars are assessed on actual weight of vehicle, trucks on rated useful load capacity—More than 200 makes of vehicles licensed in state and some vehicles out of production for several years are listed in considerable number by State Secretary. 200 cars built by the present owner.

**T**HE new license system for motor cars and trucks is in effect in Kansas. This system is based upon the weight of the car, or the carrying capacity of the truck. Licenses are being issued for the half year and beginning Jan. 1 the licenses will be issued for the full calendar year, bringing this state into line with most other states.

The license fee is \$8 for cars of less than one ton gross weight, with 50 cents added for each 100 pounds above one ton. Cars of the Ford class take the minimum fee. The fee for the Buick five passenger car is \$13. All of the money paid by the motorists for licenses, except 50 cents, goes into the road fund of the county where the car is owned. The 50 cents is taken for the administration of the law.

At the close of the old license year, June 30, there were 287,384 motor cars and trucks in the state, against a registration of 265,396 a year ago. There were 2166 dealers registered separately. This is a loss of 78 dealers from the registrations of the previous year. There were 3398 motorcycles registered and 34 dealers, while a year before there were 4220 motorcycles and 42 dealers.

There were 19,460 trucks registered during the past fiscal year. Heretofore the truck has paid the same license fee as a passenger car. The new license fee for trucks starts at \$15 a year for trucks of less than one ton carrying capacity and gradually increases up to \$100 a year for trucks of five tons or more.

On the basis of the population in March, Kansas has a car for every 6.19 persons in the state.

There are more than 200 makes of cars and trucks operated in the state. The Secretary of State listed 183 makes of cars and trucks and then had 597 cars of nondescript or obsolete manufacture. There are nearly 200 cars operated in Kansas under the name of the owner and builder. These builders have taken parts from several wrecked or fire damaged cars and have constructed themselves a motor car that runs and gets them to where they want to go. The railroads and express companies frequently hold sales of motor parts which are purchased by practical mechanics and built into cars. The speediest car making the Kansas racing circuit this year is built with two motorcycle engines, a Ford chassis and the wire wheels from a Saxon. It is chain driven and the chain was manufactured from pieces of old starter chains. Such cars as this are listed under the name of the owner.

Now the least interesting information in this report is the number of orphan cars in use in this great farming state. It will be noted that a considerable number of the cars made by companies which quit production in the slump of 1912 and 1913 are still in use and in some cases there are more of the old cars than the recent ones of the same class on behalf of which an active sales campaign has been waged. This information is only occasionally available from the official records of the registration bureaus of the states.

The following is a list of makes of cars and trucks prepared by the Secretary of State, one \* indicating a truck, while two \*\* indicate both trucks and passenger cars are included in the figure given:

# Trials of German Carbureters for Using Non-Volatile Fuels

Sixteen makes participate in competitive tests made partly on the road and partly on the laboratory testing stand. Two winning instruments are here described. Both of these are of simple design and easily adjusted.

By Benno R. Dierfeld

SOME time ago a national competition of carbureters for passenger cars and trucks was held in Germany under the auspices of the German Automobile Testing Committee and the largest German automobile club, the Allgemeiner Deutscher Automobil Club. As pointed out in a previous article by the author, fuels and fuel mixtures of very low volatility and generally of very different qualities are being used in Germany, and it was therefore considered a good plan to hold a contest to determine which carbureters were able to use these heavy fuels with the least trouble and in the most economical manner. With a good carbureter there should be little or no smoke at the exhaust, even with the heaviest fuels; the engine should start readily, should be flexible in operation and should give sufficient power. Furthermore, the carbureter should permit of changing from one fuel to another, as from a gasoline-alcohol to a benzol-kerosene mixture, without trouble and without requiring any great amount of adjustment. The results of the competition have just been published, and the winning carbureters undoubtedly come nearest meeting the present requirements, at least with the fuels available in Germany.

Sixteen different makes of carbureter participated in the competition, which was divided into three parts, a road test, a bench test and rating of the merits of design by the jury. The road test was held on a rather hilly course near Berlin and extended over a period of one week. The carbureters under test were fitted to 4½-

ton trucks with 45 hp. engines. During the first two days a mixture of benzol and heavy oil was used for fuel; on the next two days a benzol-kerosene mixture and on the final day, for the sake of comparison, benzol alone. The heavy oil was gas oil, a product of petroleum distillation, with an end point of 680 deg. Fahr. The kerosene was not the ordinary lamp oil, but a heavier product obtained by the distillation of the heavy oil above mentioned.

A great deal of importance was attached to the road test, because the spark plugs were regularly examined as to fouling and the exhaust observed as regards smokiness, hence it was possible to check the character of the combustion. Emphasis should be laid on the fact that all the trucks ran with a practically clean exhaust. The engines were idled with the trucks standing and they were started up under different conditions, and all observations were noted. It was also observed whether or not it was necessary to change nozzles in the course of the contest, and if no exchange was made this was set down to the credit of the carbureter. The road test ended with a run up a 5 per cent incline  $\frac{5}{8}$  of a mile in length to test the pulling power of the engine.

Bench tests were made at the automobile laboratory of the Dresden Technical University, under the direction of two professors. Owing to difficulties with the fuel supply, it was impossible to obtain the different grades of fuel which it had been intended to use for these tests, and a mixture of 30 per cent benzol and 70 per cent kerosene was used, the conclusion being

reached that this poor fuel, in conjunction with the different fuels used during the road tests, would permit of fairly judging the qualities of the carbureters. Entrants were required to furnish one carbureter for each bench test of the series, and the carbureters were fitted in the presence of a representative of the entrant. No changes in the carbureters were permitted after delivery to the contest authorities, except replacements of venturi tubes and fuel nozzles during the preliminary tests.

The brake tests were made on a Daimler valve-in-head four-cylinder 4.14 x 5.90 in. truck engine developing 35 hp. at 1,000 r.p.m., and on an Audi L-head four-cylinder 2.95 x 4.65 in. passenger car engine, developing a maximum output of 22 hp. at 2200 r.p.m. A water brake was provided for the truck engine and an

Sectional views of the Homa carburetor, one of the winners in the German carbureter trials.

adjustable fan brake for the passenger car engine. The brake tests were divided into preliminary and main tests, and during each of these tests exhaust samples for analysis were taken and the spark plugs were examined. The preliminary tests served only to obtain the best possible adjustment of the carburetor and did not count in the results of the contest. The main tests included determination of the fuel consumption per horsepower-hour under wide open throttle condition at different engine speeds, determination of the fuel consumption per horsepower-hour at constant engine speed with gradually increasing load, determination of the lowest idling speed without change of carburetor nozzle, determination of the fuel consumption under these conditions and determination of the acceleration of the passenger car engine. Every test run had a duration of 10 minutes; then an exhaust gas sample was taken.

In the rating of design, points were allowed for different features, including special equipment, simplicity of design, low idling speed, lightness, accessibility of nozzle, etc. The preliminary work in connection with this part of the competition was done by experts selected by the jury. The jury consisted of ten members, including the leading carburetor experts of Germany. In making the awards, the results of the bench tests were given double weight as compared with the more practical road tests, one reason for this procedure being that in the bench test each carburetor was tested on two different engines. The result of the contest was a tie for first place between the Homa carburetor manufactured by the Homa Co. of Berlin-Halensee, and the Einhorn carburetor manufactured by the firm of Dehle & Severin, Gütersloh, Westphalia. The result was somewhat of a surprise, for the reason that the Einhorn carburetor was a newcomer and had been heard of very little before the trial.

Figs. 1 and 2 are two sectional views of the Homa carburetor, a make well known in Germany and widely used. Fuel enters the float chamber through tube E and the interchangeable seat of the float valve Q. Within the float chamber is located the conventional brass float K with balance levers O. The cover L of the float chamber is fixed in position by the knob D and flat spring C.

From the float chamber the fuel flows through passage Y to a hub X, by means of which the float chamber can be swung around into the most favorable position with respect to the engine. The lower part of the carburetor contains the fuel strainer a, which can be detached and cleaned after removing nut Z. The fuel from the float chamber passes through the single fuel nozzle b. This nozzle, which is rather long, has the fuel metering opening at its lower end and the calibrated correcting air nozzle c at its upper end.

The fuel enters the annular space between fuel nozzle b and the carburetor case, and fills up the main nozzle opening p leading to the throttle chamber. At the same time, however, the idling passage d (Fig. 2) provided with the calibrated bushing e, is filled with fuel up to a predetermined level. The throttle valve h with stop screw W is arranged in the usual manner and can be removed by detaching the cover plate T, but the throttle valve is of peculiar shape, having a nose Z on the regulating edge.

If the throttle is only slightly opened, as indicated in dotted lines in Fig. 1, then the main nozzle p is covered

FIG. 3

FIG. 4

Two sectional views of the Einhorn carburetor which tied with the Homa in winning the German carburetor trials.

up, and during the suction stroke of the engine fuel is emitted only from the idling nozzle m, connecting the idling passage d with the throttle chamber, mixing with the high velocity air stream entering through the main air inlet R, thus producing a very rich mixture. Of course this fuel supply lasts only a short time. Thereafter air enters through the correcting air nozzle and no more pure fuel but a fuel fog consisting of little fuel and much air is sprayed through the idling nozzle m; in this manner the mixture is automatically weakened, while at the same time the fuel is thoroughly atomized at idling speeds. In the same measure as the throttle valve is opened, the main air entrance R and the main fuel nozzle are opened and regular operation begins.

The other prize-winning device, the Einhorn carburetor, is shown in the sectional views, Figs. 3 and 4, with the throttle valve in two different positions. Fuel passes through tube A to float chamber B, the fuel level of which is regulated by balance weights and a needle valve in the ordinary manner. The fuel level can be easily adjusted after removing nut C. The lid of the float chamber can be quickly detached in the same manner as in the Homa carburetor. From the float chamber the fuel flows to the calibrated nozzle D, and then to the atomizer E, detachable from below, provided at the top with one axial and several radial openings.

When idling, the throttle valve F occupies the position shown in Fig. 3. The top part of the atomizer E then projects into the passage G of the throttle valve F and fuel is drawn only through the axial opening of the atomizer. This fuel mixes in the passage G with the high-velocity air entering through main air inlet H, thus forming a rich mixture. After a short time the fuel in the idling passage I is exhausted and additional air enters through the correcting air nozzle J, whereupon a fuel fog is sprayed from the central opening of the atomizer E. In this manner the mixture is automatically weakened for normal operation, and yet the fuel is thoroughly atomized when running idle. The idle running screw K in the throttle valve F, accessible after removing the cap screw L, serves for the low-speed adjustment and is screwed in further if the mixture is too rich, and out if the mixture is too lean, a corresponding addition in the air being made by adjusting the stop screw of the throttle valve. If the throttle valve F is opened wide, then all radial openings of the atomizer E are uncovered in proportion to the area of the passage from the main air inlet H to the outlet opening M.

# New British Chassis Incorporates Many Novelties

Leyland chassis has eight-cylinder-in-line engine possessing some unusual features. All chassis parts are lubricated from one central point. Other departures from conventional practice include vacuum-operated foot brake, twin bevel drive in rear axle and peculiar spring suspension.

By M. W. Bourdon

**I**N the number of its departures from standard practice it would be difficult to imagine any more pronounced than the new eight-cylinder-in-line Leyland, which is the product of the well-known British truck makers. Ignoring the arrangement of its cylinders, which are cast as a block with the top half of the crankcase, the overhead camshaft drive is an innovation. By skew gearing from the rear end of the crankshaft is driven a short longitudinal half-time shaft bearing three narrow eccentrics, and by means of three connecting rods, 16 in. long, coupled to these, and three similar eccentric disks at the rear end of the camshaft, the latter is rotated; the units of each group of three eccentrics are, of course, set at 120 deg. relative to each other. A costly job, but in that respect resembling many other features of this chassis, which is offered at approximately \$12,000, with an output of eighteen planned for 1921 and 200 for 1922.

The overhead valves are operated by roller-end rockers and are held up to their seatings by flat steel laminated springs, each of the latter serving for the two valves of a cylinder and the longest leaves having slotted ends applying under T-headed studs screwing over the threaded valve stems. Each spring has 11 leaves, varying in length from one to six inches.

A dry sump system of engine lubrication is used, but the oil is picked up by the flywheel instead of by a sec-

ond pump to return it to the rectangular aluminum tank at the side of the top half of the crankcase. A pump in the tank delivers the oil under pressure to the hollow crankshaft and to all parts of the chassis—following the lead of the Ferguson in the latter respect. A spare oil tank on the dashboard maintains a constant level in the engine tank, while another replenishes the gear-set. Alongside these is a 4-gallon vacuum tank usable for gravity feed with direct replenishment in emergency.

Water is circulated by pump with thermostatic control between radiator and engine—a feature of note being that the fan behind the honeycomb radiator is driven through a clutch which is thrown out of action at small throttle openings.

The steering column, with an excessive rake, finishes at the dashboard, to which the gear housing is attached; thence a vertical shaft with the steering lever at its lower end conveys the motion to the drag link. A single disk clutch and a flexible coupling carry the drive to the gear-set, the casing of which has a trunnion bearing at each end in U-glands, with square section leather packing, formed in the holes of two deep cross members. Except that the box is prevented from turning by two dowels or keys, it is free to "float" to accord with or counteract the effects of frame distortion.

The propeller shaft is divided, the front half being open and having two laminated steel joints, rectangular

Right—New eight-cylinder-in-line Leyland engine. Overhead camshaft is driven by eccentrics. Fan clutch is disengaged automatically at low throttles. Four gallon gasoline tank and reserve oil tanks are set in dash.  
Left—Front spring suspension on new Leyland, showing radius member which is keyed to front cross-shaft enclosed by concentric tube. This shaft acts as a torsional spring and is intended to check rolling

plates connecting the star pieces instead of disks. The torque tube inclosing the rear half of the shaft is supported in a spherical housing in a cross-frame member.

A twin bevel drive occurs in the back axle, the differential being on the rear end of the propeller shaft. Straight-toothed bevels are used, while the driving shafts and the wheels are splayed.

Both brakes apply within the rear wheel drums, but the pedal-operated shoes are actuated by a vacuum device. Movement of the pedal allows engine suction to take effect upon a piston in a cylinder below the pedal, the latter having 5 in. of travel before the full braking effect occurs.

The suspension is distinctly out of the ordinary, for an endeavor has been made to prevent rolling by linking up the pairs of springs by torsion shafts. Thus at the front, where semi-elliptics are used, the spring ends are free to slide in brackets fore and aft. A steel drop forging of H-section forms a radius member at each side, extending from front extremity of frame to the axle. The fore ends of both links are keyed to a cross shaft inclosed by a concentric tube; thus when one

spring is deflected, or when one is deflected more than the other, the cross coupling shaft is submitted to a torsional stress and yields to it, but acts as a flexible check. The shaft is approximately 1 in. (25 mm.) in diameter and is not intended, like the Wolseley Six cantilever rear spring coupling tube, to resist torsional stress and compel the opposite spring to check the one deflected.

At the back the Leyland has quarter-elliptic springs, to which the same principle is applied, but in this case the torsion shaft is secured to the butt ends, which have a trunnion bearing in a frame bracket.

The foregoing gives a general idea of the scheme for improving spring suspension; there are what the designer terms refinements, which do not affect the principle, but which cannot be described in a few words without drawings. Frankly, the writer must admit he is not impressed as to the advantages derivable. They may exist, but not, he suggests, to a degree which warrants the somewhat involved departure from normal practice. For example, one of the "refinements" referred to limits the total deflection of the springs, but, it would seem, to no better effect than a simple rubber buffer.

## Detachable Fairleads for Aircraft

A FAIRLEAD, in aircraft construction, is a guide and support for the control cables connecting the pilot's levers with the flying control surfaces, or engine spark and throttle levers. Ordinarily these are metal tubes, brazed or soldered to a sheet metal clip for attachment to the aircraft structure, and threaded over the control cable. As such, the fairlead serves to hold the cable in line between pulleys, or to offset the lead to avoid interference with other parts, where the offset is insufficient to render a pulley advisable.

The Williams detachable fairlead, in addition to fulfilling the above functions, permits the cable to be removed or replaced at will. A single fairlead is shown in Fig. 1. It will be noted that the fairlead comprises a split composition guide held in a metal base, and locked in place by a wire. The method of operation is clearly shown.

Expansion of the number of guides held in a single base is readily possible, with retention of the detachable feature. A compound base, used for spark and throttle controls on a tandem engine installation is illustrated in Fig. 2. Following are the advantages claimed for this type of fairlead:

1—Control cables can be made up in production prior to the attachment of fairleads, and the fairleads attached to the aircraft structure during construction. 2—The composition guide presents a slow wearing, non-corrosive

surface with inherent lubricating qualities to the control cables. Control cable wear is reduced, and in event of wear to the guides, replacement is readily accomplished. 3—Replacement of control cables is facilitated, and erection or tearing down the aircraft can be accomplished with a minimum of work. Replacement cables can be made up complete in the shop, thus avoiding leaving one end open to be made up at the field on assembly. 4—Light weight, standardization and low cost.

According to the inventor, S. T. Williams, of Philadelphia, in one installation where the detachable fairlead replaced an ordinary fairlead, cable life was increased from 18 hours flying time to over one hundred.

In a laboratory test, a fairlead was set up with a 6 in. cable offset in 3 ft., and under a 100 pound pull on a 7 in. stroke, 70 strokes per minute, ran for 75 hours without noticeable cable wear. No lubricant was used. The test was discontinued only because the cable was fraying where it passed over a pulley before going onto the fairlead. Though the fairlead was deeply grooved, it was still in condition for many more hours of service.

Ordinarily only two sizes of fairleads are required—one for flying control cables, and one for engine and accessory controls. These have been standardized for the single base mounting. When compound mountings are required, standardized guides are used.

Fig. 1—Single Detachable Fairlead

Fig. 2—Compound Detachable Fairlead

# Influence of Various Fuels on Engine Performance

## Part IV

When all fuels are used with same compression ratio power output is proportional to energy content of charge, but fuels which can be used with higher compression ratios without detonation are capable of developing higher maximum power than those which detonate at lower pressures.

By H. R. Ricardo\*

**T**HE power output obtainable from different fuels must be regarded from two points of view:

(1) When all fuels are used with the same compression ratio.

(2) When the compression is adjusted to suit each fuel, the ratio of compression being the highest consistent with freedom from detonations under any normal circumstances.

We will deal first with the results obtained at a constant compression ratio. Under these conditions, provided that each fuel is burned at the same efficiency (and it will be shown later that this is the case), the power output will clearly be proportional to the energy content of the fuel-air mixture. This energy content will be equal to the product of the heat of combustion of the fuel, when burnt with the requisite quantity of air, and the change in specific volume. By change in specific volume is meant the increase or decrease of the number of molecules in the working fluid during combustion. It is clearly necessary to take account of this in calculating the total internal energy of the burnt fuel-air mixture, since at the same temperature the pressure will be proportional to the number of molecules.

### Heat of Combustion of a Fuel-Air Mixture

This is probably best expressed in terms of foot-pounds of heat energy liberated by the combustion of 1 cu. in. of a mixture of fuel and air measured at standard temperature and pressure, the mixture being in all cases of such proportions that all the oxygen in the air is combined.

As pointed out previously, the heat of combustion of a fuel-air mixture as defined above has no direct relation to the calorific value of the fuel.

Table VII gives the specific gravity, the calorific value in terms of weight and volume, also the heat of combustion of a number of different hydrocarbons, which form the principal ingredients of nearly all the available volatile hydrocarbon fuels and some other combustible substances.

From this table the heat of combustion of almost any volatile liquid fuel can be arrived at once its chemical composition has been determined.

The change in specific volume varies, of course, with the composition of the fuel; it varies also with the mixture strength. In the case of all fuels belonging to the

general group known as petrol, the specific volume after combustion is substantially greater than before, thus giving a net increase in the total internal energy. In the case of benzol and other members of the aromatic group there is only a slight increase in specific volume, while in the case of hydrogen, carbon disulphide, acetylene, etc., there is a substantial decrease.

Table VII gives values for the following:

Column E.—The change in specific volume after combustion of a mixture of fuel and air in such proportion as to give complete combustion without excess of air.

Column F gives the total energy liberated by combustion in terms of foot-pounds per cubic inch, taking into account the change of specific volume, and again assuming that the proportions of the mixture are such as to give complete combustion. Column C of Table VIII may therefore be taken as an expression of the power output obtainable from each fuel, assuming:

(1) That the mixture strength is that giving complete combustion.

(2) That the fuel is completely vaporized before entering the cylinder.\*

(3) That the temperature of the mixture after complete evaporation is the same for each fuel.

When an over-rich mixture is used, and the fuel is only partially burnt, the heat of combustion of the mixture will be no greater, but the increase in specific volume will in most cases be larger, and therefore the total internal energy will be somewhat greater on this score; therefore a slight increase in power might be expected in the case of those fuels having a relatively large increase in specific volume. On the other hand, when an over-rich mixture is used the products of combustion so formed have a higher specific heat, and this, in nearly every case, counteracts the advantage which would otherwise be obtained from the increase in specific volume. In practice, with, perhaps, the single exception of the alcohol group, very little, if any, increase in power is obtained by using a mixture richer than required for complete combustion.

\*NOTE.—This will only be true, strictly speaking, if Column D of Table VII is calculated using calorific values of the fuels burnt in a state of vapor. Bomb calorimeter experiments give calorific values from a liquid state, therefore to the usual calorimetric figures should be added the latent heats of evaporation. Strictly speaking, there should be added only the latent heat at constant volume, which is the usual latent heat (at constant pressure) less  $p_v$  (expansion on vaporization). This latent heat is apparently about  $\frac{1}{45}$  of the figure at constant pressure. Latent heats are almost certainly observed at atmospheric pressure, so that the amount to be subtracted will be simply  $\frac{14.7 \times 144}{778}$  (specific volume of vapor at normal B.P.).

\*From a preliminary report on research work conducted by the author and other investigators for the Asiatic Petroleum Co. and published in *The Automobile Engineer*.

An examination of Column F of Table VII reveals the very interesting fact confirmed by numberless experiments that the power output available from all known volatile hydrocarbon fuels is the same to within narrow limits provided (1) that they are all tested at a compression ratio at which full ignition advance can be used without detonation, and (2) that the losses due to change in specific heat and to dissociation at high temperatures are the same in all cases. In this connection Messrs. Tizard and Pye's investigations prove that there is very little to choose in this respect between the combustion mixtures of any of the available fuels.

The experimental results, a résumé of which will be given later, and which cover a very large number of independent tests, have completely borne out the conclusions arrived at from Messrs. Tizard and Pye's theoretical investigations of the chemical properties of the fuels and of the process of combustion. All the experiments have proved conclusively that, so long as the fuel is completely evaporated, the maximum power obtainable from samples of each of the groups given in the above tables, or from any combination of them, is proportional to the energy content, and, excepting only the alcohol group, is the same to within less than 3 per cent. The differences in the losses due to dissociation and to change of specific heat that do exist are such as to minimize the differences between the heats of combustion of the different types of fuels (paraffins, naphthenes, aromatics, etc.), and to place them still more nearly on a par.

There is, however, one variable factor which has been mentioned previously, and which, so far as the writer is aware, has not been taken into consideration by other experimenters, namely, the influence of the latent heat of evaporation upon volumetric efficiency. This factor was found, in the case of alcohol and the other members of this group, to have a very powerful influence on the maximum power output obtainable.

The conclusions given so far are based on the assumption that the whole of the fuel is evaporated before its entry to the cylinder—in practice this is seldom, if ever, the case. It is, of course, clear that the weight of charge taken into the cylinder will depend upon and be inversely proportional to its absolute temperature at the moment when the inlet valve closes. There is definite evidence from experimental results that, with the exception of alcohol and the other members of its group, all fuels boiling below 200 deg. C. (392 deg. Fahr.) are completely evaporated before the commencement of the compression stroke by contact with the hot walls and admixture with the highly heated residual exhaust products in the cylinder excepting only a very small proportion which may enter the cylinder in coarse drops, and so not only escape evaporation, but even to a large extent combustion also. This proportion is, however, quite insignificant, and has no influence so far as power output is concerned.

The absolute temperature, therefore, at the commencement of the compression stroke is dependent upon (a) the amount of external heating applied, and (b) the latent heat of evaporation. It is almost independent of the temperature of the charge during its entry to the cylinder. In fact, the final absolute temperature, and, therefore, the weight of the charge taken into the cylinder is dependent upon the quantity and latent heat of the fuel, and upon the amount of heat added to it, external to the cylinder—it is substantially independent, either of the volatility of the fuel, or its entering temperature.

For example, a highly volatile fuel entering the cylinder at 0 deg. C., (32 deg. Fahr.), and a heavy fuel of low-vapor tension entering at 30 deg. C. (86 deg. Fahr.), will both have the same final absolute temperature at the commencement of compression, if the latent heat of both is

the same, and if both charges received the same amount of pre-heating. In the former case most of the evaporation has taken place outside the cylinder, and the added heat has been absorbed by the latent heat of the vapor, in the latter case little or no evaporation has taken place outside the cylinder, and the added heat has therefore raised the temperature of the air and the still liquid fuel. In both cases contact and admixture with the highly heated exhaust products in the cylinder will complete evaporation, and in both cases the final temperature will be the same, hence the weight of working fluid (which is inversely proportional to the absolute temperature), and therefore the power output, will be the same in both cases.

From the above considerations it will be seen that, with any given amount of pre-heating (provided it is not excessive), the volumetric efficiency, and therefore the power output, will vary directly with the latent heat of the fuel.

The writer has deemed it advisable to emphasize this point very strongly, because he was at first misled into supposing that the final suction temperature was proportional to the inlet temperature, as it would be in the case of a gas engine. The above conclusions may be summed up as follows:

(1) The power output is inversely proportional to the absolute temperature of the working fluid at the end of the suction stroke—since it is the temperature at this point which controls the weight of charge, and therefore the volumetric efficiency.

(2) Other things being equal, the final suction temperature is controlled by the amount of external heating, on the one hand, and the latent heat of the fuel on the other; it is nearly independent of the temperature of the entering charge or its volatility.

Starting with a mixture of fuel and air at atmospheric temperature, heat is added by (a) contact with the inlet valve and hot walls of the cylinder, (b) admixture with the residual exhaust gases in the combustion chamber, and by (c) external heating of the carburetor or induction system. Heat is abstracted by (d) the latent heat of evaporation of the fuel; (a) and (b) may be regarded as constant, and, for the purpose of the present argument, may be ignored. For any given fuel, therefore, the power output obtainable is controlled primarily by the amount of heat added to the working fluid before it enters the cylinder, and, so far as power output is concerned, it is immaterial whether the heat so added is devoted to raising the temperature of the mixture or to evaporating the fuel at low temperature. Conversely with any given amount of pre-heating, the power output obtainable is dependent upon the latent heat of evaporation of the fuel.

Apart from the alcohol group, the variation in latent heat is not very large, and does not exercise any appreciable influence. It is interesting to note, however, that in cases where the total internal energy is lower, the latent heat is generally slightly higher; consequently a slightly greater weight of charge is taken into the cylinder, sufficient in most cases to compensate for the lower internal energy, and thus bring the actual power output to substantially the same in all cases. This point is well illustrated by the instance of benzol, as will be seen at once by reference to Table VII. The energy liberated by combustion of a cubic inch (at standard temperature and pressure) of benzene-air mixture is appreciably lower than that of the hydrocarbons forming the greater proportion of gasolines. On the other hand, the latent heat of benzol is considerably greater, and as the result the power output obtainable from benzol is the same as that from gasoline to within less than half of 1 per cent.

Table VII gives the latent heat of evaporation of a num-

ber of hydrocarbons and other substances enumerated in the previous tables. The air-to-fuel ratio by weight, also the drop in temperature of the mixture due to evaporation of the liquid, is shown for each fuel. The calculations are made for mixtures giving complete combustion, but without excess of air.

In the case of alcohol, owing to the very much higher latent heat and to the fact that the proportion of fuel to air is also much greater, the latent heat of evaporation plays a supremely important part, and results in a really marked increase in power as compared with other fuels, although its total internal energy is lower than that of either gasoline or benzol. Moreover, there is introduced a feature which is not observed to any marked extent with other fuels—namely, that the power output increases very considerably when an over-rich mixture is used, because more fuel is then evaporated, the temperature of the charge is lowered, and the gain in weight of charge or volumetric efficiency considerably more than outweighs the loss due to the greater specific heat of the products of combustion.

Apart from the variations due to the differences in the latent heat of evaporation of fuels, which only assumes important proportions in the case of alcohol and the other members of that group, all tests proved that the power

output obtainable was, in fact, directly proportional to the total internal energy of the fuel, and this was further confirmed by the fact that the thermal efficiency at any given compression ratio was found to be the same with all fuels boiling below 200 deg. C. (392 deg. Fahr.), except the alcohol group. That is to say, it was found that each fuel was burnt at the same efficiency, and, therefore, the same proportion of its internal energy was converted into power. In the case of the alcohol group the efficiency was found to be slightly higher, and a further increase in power output was obtained thereby.

There was clear evidence that in the case of the alcohols, owing to the very high latent heat, evaporation continued throughout the compression stroke also, with the result that the compression was nearly isothermal. As a result the temperature of the cycle was lowered, the losses due to conduction and to change of specific heat were reduced, and the efficiency was slightly increased thereby. This feature became particularly prominent in the case of methyl alcohol, which has the highest latent heat of any of the fuels tested, and since it has also the lowest calorific value it follows that the weight of fuel per cycle is greater than with any of the others. Both the power output and efficiency obtainable with methyl alcohol were considerably greater than with any other fuel examined.

In referring to alcohol and allied substances as fuels it should perhaps here be explained that though these fuels give a considerably greater maximum power output, and, furthermore, can be used with a higher thermodynamic efficiency than either gasoline or benzol, the

heat value of the alcohols per unit of weight or per unit of volume of the liquid is so much lower than that of gasoline or benzol that the rate of consumption for equal power output is nevertheless greater. The exact amount of this larger fuel consumption with alcohol, as compared with gasoline or benzol, will be examined later when dealing with the subject of efficiency.

In Table VII is given (Column J) values for relative power output calculated directly from the foregoing tables and in accordance with the argument adduced above in arriving at the conditions governing power output. As will be seen by a glance at this table, the greatest difference among the paraffins, aromatics and naphthenes is hardly more than  $\pm \frac{1}{2}$  per cent. This deduction, as will be seen later, is corroborated almost exactly by the experimental results.

With a view to determining definitely the power output obtainable from each fuel at the same compression ratio, several hundreds of tests were run both on the variable-compression engine and on the supercharging engine. In all cases the procedure adopted was as follows:

A suitable compression ratio was chosen at which it was known that none of the fuels to be tested would detonate under any conditions of mixture strength or ignition advance. The engine was first started up either on the specially prepared aromatic free gasoline, or on pure benzol, which was adopted as the standard fuel for high-compression work. It was then run with wide-open throttle at a speed of 1,500 r.p.m. until the temperature of the jacket water, carbureter, lubricating oil, and induction pipe had settled down to constant values.

The best ignition setting and mixture strength for the development of maximum power on the fuel were, of course, well known from previous experience, but no readings were recorded unless or until the torque was within  $\pm 0.3$  per cent of that known to be obtainable with the standard fuel (after correction for barometer).

So soon as the running conditions were considered to be in every respect normal, and the engine was found to be developing standard power with standard settings, the fuel was changed over to the sample to be tested; the correct mixture strength and ignition setting for the development of maximum power with the new fuel were found, and readings of torque were taken. In some cases the torque curve over a wide range of speed, generally from 800 r.p.m. to 1800 r.p.m., was explored, but this practice was discontinued later after it had been found from repeated experiments that the characteristic of the torque curve over the whole available range of speed was the same for every fuel tested (provided, of course, that the correct mixture strength and ignition setting was used for each speed).

The maximum power output obtainable from each sample of fuel was determined in this manner, the time taken to find the best settings and secure steady and reliable readings being about half an hour in each case.

During the whole period of such a series of tests the throttle remained wide open, and great care was taken to prevent any variation in temperature either of the circulating water or the heat input to the carbureter.

After completing a series of such tests on a number of different samples, a final test was always made on the standard fuel, when, with the same temperatures throughout, and the original adjustments for this fuel, the power output had to return to within less than 0.5 per cent of the initial reading, or the tests were discarded as unreliable. In such tests only one variable remained, namely, the temperature of the lubricating oil, which always rose slightly during a prolonged run of the nature just described. In the case of the variable-compression engine, owing to the extensive use of ball bearings and

other precautions, the oil temperature had no appreciable influence on the performance of the engine, but in the case of the supercharging engine the friction losses diminished perceptibly as the oil temperature rose, and a small correction seldom exceeding 0.4 per cent had to be made for this factor. Great care was, of course, taken to ensure against any variation in the character of the oil supplied. A large stock of lubricating oil was prepared and set aside for the purpose of these tests in order to ensure uniformity throughout.

At the conclusion of each series of tests the engine was motored by means of the balanced electric dynamometer in order to check the mechanical losses.

For the sake of uniformity all figures are given in terms of indicated horsepower, indicated thermal efficiency, etc. This was found desirable because of the differences in mechanical efficiency between the several engines upon which the tests were carried out. The mechanical losses of the engines used were ascertained very carefully by both direct and indirect measurements, and, once determined, and variation could be detected at once by the motoring test. In the case of the variable-compression engine no measurable change occurred after the first thirty or forty hours' running, but in the case of the supercharging engine slight variations in friction were noted from time to time, due probably to slight distortion or lack of rigidity in the structure of the engine.

The power tests at constant compression were run under three different conditions, namely:

(1) With no heat supplied to the carbureter.

(2) With a constant heat supply of 65 B.t.u. per minute when running at 1500 r.p.m., or 0.0433 B.t.u. per

minute per revolution per minute when running at speeds other than 1500 r.p.m.

(3) With the heat supply varied to maintain the entering gases at a constant temperature of 15 deg. C. (59 deg. Fahr.) as measured\* by a thermometer in the induction pipe and close to the inlet valve.

In Table VIII is given the mean results of a very large number of tests taken on the variable-compression engine, with the different temperature conditions referred to above.

Since in this table are given actual experimental results, the fuels enumerated are of necessity only those of which fairly large quantities could be obtained—very few chemically-pure hydrocarbons are obtainable in any quantity. The substances given here are the same as those included in Table II.

In view of the fact that in most engines the heat supply to the carbureter may be regarded as more or less constant, the results obtained under the conditions shown in Columns F and H are the most important and the most nearly allied to practice. The results shown in Columns G, I and K are interesting in that they give an indication of the volatility of the fuels.

In this table, Columns B, C and D show the approxi-

\*The figures given for the temperature of the working fluid as it enters the cylinder must be regarded as a first approximation, and are only strictly accurate when the whole of the fuel is evaporated before it reaches the thermometer bulb. There can be little doubt that when unevaporated fuel is present the thermometer acts as a "wet bulb" thermometer, and therefore gives readings which are below the true value. No means have yet been found for measuring accurately the temperature of the working fluid when a portion of the fuel is unevaporated. As explained previously, the actual temperature of the working fluid during its entry to the cylinder is relatively unimportant, for it is the total heat input which controls the volumetric efficiency, and therefore the power developed.

Note.—Experimental observations of the calorific values of liquid fuels are made in a "bomb-calorimeter" in which the fuel before combustion is liquid and the products of combustion are cooled down to room temperature. The observed heat, therefore, includes the heat of condensation of the steam formed during combustion, the subtraction of this gives the "lower" values tabulated above. If the fuel before combustion had been in a state of vapor, the observed calorific values would be greater than those given, by the heat needed to vaporise the fuel in the bomb.

Note.—The above values columns E and F are calculated for an Air-Fuel mixture just giving complete combustion, at a temperature of 0° C. and absolute pressure of 29.92 in. of mercury.

Column I is calculated assuming specific heat of the fuel vapor is constant for all at 0.5.

Relation between I.M.E.P. and fuel consumption for different fuels at the same compression ratio which is sufficiently low to permit of each being used under the most economical conditions for that compression. Curve (A) is with aromatic free gasoline (S.G. .718). Curve (B) is with "A" gasoline (S.G. .782). Curve (C) is with benzol (S.G. .880). It will be seen that while the minimum consumptions vary widely, depending (at this low compression) solely on the heat values of the respective fuels, the maximum I.M.E.P., and therefore also the power output, is

practically the same for each of these very different fuels

mate composition of each of the fuels on which power output was observed. From the composition of each fuel has been calculated (Column E) a figure of merit for power output which is exactly comparable with the values given for relative power output (Column J of Table VII) deduced for the pure substances in manner described. It will be seen that it is only for fuels (such as the alcohols) with unusually high latent heat that the observed power output (Columns H or F given in terms of indicated mean effective pressures) fall short of the calculated figures of merit (Column E). Column M gives the observed power output in terms of indicated mean pressure for each of the fuels under equal conditions of heating, but after full advantage has been taken of increasing the compression ratio up to the limit set by detonation or by pre-ignition for that particular fuel.

From the tables given above and from numerous other experiments of a similar nature to those recorded here, certain definite conclusions may be drawn.

With the exception of ethyl alcohol and methyl alcohol, which, on account both of their high latent heat and relatively large increase in specific volume, behave somewhat differently, and require special consideration, the following facts may be considered as having been established past all doubt. Mostly, they were arrived at first by purely theoretical reasoning, and have since been confirmed by actual tests carried out under conditions which ensure a very high degree of accuracy.

(1) That within very narrow limits the power output obtainable from any volatile hydrocarbon fuel or from any combination of such fuels is substantially the same when used with the same compression ratio provided that the compression ratio is sufficiently low to permit of each fuel being used to its full advantage for that compression.

(2) That so long as the ignition timing is adjusted to suit the normal rate of burning of the fuel the relative power output is the same at all speeds, i.e., there is no evidence to show that certain fuels giving more power relatively to another at low speeds, do not also give more power at high speed. This is shown in Fig. 9.

(3) That maximum power is always developed when the mixture strength is at or near that giving complete combustion. (See Fig. 10.)

(4) The power output obtainable from any fuel or combination of fuels when the heat supply is constant, or, more strictly, when it is proportional to the latent heat of evaporation of the fuel, is directly proportional to the energy content of the combustible mixture from which it would appear that the efficiency with which all fuels are

burnt is the same. It will be shown later, when dealing with efficiency, that within narrow limits this was found to be the case.

In the case of alcohol and the other members of its group these conclusions require certain modification on account of their high latent heat.

In the case of the alcohol group the conclusions may be stated as follows:

(1) Owing to their low boiling-point it is unnecessary to provide much external heating; consequently the bulk of the fuel enters the cylinder in a liquid state, with the result that the temperature of the charge is lower, and the power output obtainable is considerably greater than from other fuels, although their total energy (see Table VII, Col. F) is actually somewhat lower.

(2) There is no evidence to show that their low rate of burning has any adverse influence on the power obtainable at very high speeds or very low compression ratios.

(3) Again, owing to the high latent heat and relatively large increase in specific volume, the power output obtainable increases as the mixture is enriched, and continues so to increase until the mixture strength is at least 20 per cent more than that required for complete combustion. (See Fig. 11.)

(4) Owing to the fact that in the case of this group, and this group only, an appreciable proportion of the fuel evaporates during the compression stroke, compression is more nearly isothermal, the temperature of the cycle, as a whole, is lower, and the efficiency is raised thereby. The power output is therefore increased somewhat, since a slightly greater proportion of the total internal energy available is converted into useful work.

#### Tests With Variable Compression

So far only the power output obtainable from different fuels when used with the same compression ratio has been considered. It is clear, however, that to obtain full advantage of the lower rate of burning of certain fuels each fuel should be run at the highest compression ratio it will stand without risk of detonation. For the purpose of these tests the variable compression engine proved invaluable, for the compression ratio could be varied to suit each sample within the space of a few seconds, and that without reducing either the speed or the load, or affecting any of the temperature conditions.

Although a very large number of tests were carried out extending over many months, the results obtained

Relation between I.M.E.P. and fuel consumption with gasoline and with methylated spirits (a mixture of alcohols). The results were observed under exactly equal conditions of compression ratio, heating and ignition timing. It is seen that while the minimum consumption of the methylated spirits is 55 per cent greater than for the gasoline, the maximum I.M.E.P., and therefore the power output, on methylated spirits, is 10 per cent greater also

Notes.—\* Indicates that owing to detonation occurring at a compression ratio 5:1 the value given is calculated from the observation made when running at the highest usable compression.  
† Indicates that pre-ignition and not detonation precluded the use of a higher compression ratio, the sparking plug employed being K.L.G. type F 12.

may be stated very briefly, for it was found that the relation between power output and compression ratio was precisely the same in the case of every fuel tested.

In all cases it was observed that fuels capable of

NOTE—It will be shown later that the observed thermal efficiency follows Tizard and Pye's ideal curve very closely. That the observed mean pressure does not do so, can only be accounted for by a change in the volumetric efficiency.

The full line shows the observed increase or decrease of maximum I.M.E.P., and therefore of power output when compression is varied, as compared with that obtainable at a compression ratio of 5:1. The dotted line shows what would be this relation if it were proportional to the air cycle standard—that is, if relative thermal efficiency and volumetric efficiency were constant with varying compression. It appears that both are variable, but that with increasing compression the fall in volumetric efficiency more than balances the slight rise in relative thermal efficiency.

standing high compressions give relatively to each other the same power output at lower compressions. At varying speeds up to the limit at present obtainable the relative power output of different fuels is the same.

At first sight one would naturally expect that when the compression is varied without involving any change, either thermal or mechanical, the mean effective pressure would be proportional at all times to the air-cycle efficiency corresponding to the compression ratio used. In Fig. 12 the upper curve shows the air-cycle efficiency over the range of compression from 4:1 up to 7.5:1. The lower curve shows Tizard and Pye's ideal efficiency for any fuel when the mixture strength is that corresponding to complete combustion. This latter curve takes into account the losses due to change in specific heat and to dissociation at high temperatures, but it does not take into account the direct heat loss to the cylinder walls, which is always more or less a variable quantity depending upon the form of the combustion

# Combination Roof Construction for Enclosed Bodies

The so-called combination roof is not really a new development, except as regards certain specific characteristics. The savings made possible by the use of this construction are discussed here, together with the practical design of such a roof. Suggestive diagrams are presented.

By George J. Mercer

ALL solid roofs on enclosed automobile bodies, whether made of three-ply wood, agisoté, or metal, are liable to generate a bell or drumming sound. This is due to the synchronizing of the sounds generated by the car in motion, or rather by such parts of these sounds as is carried to the body framing and to the resistance stresses that the large unbroken roof panel offers against the distortion of the body.

The ability of the solid roof panel to absorb shock with the minimum of complaint as registered in the drumming is proportionate to the increase in the arch and size of the top. If the roof has considerable camber, for instance, and the body is long enough to provide seven-passenger seating, a metal roof with a deadener of cotton wadding between the top sheet and the bows will give entire satisfaction. But there are many more five than seven-passenger bodies, while the coupes must also be taken into account. These latter are still shorter, while the tendency at present is to give them thin, flat roofs. Consequently, users of enclosed bodies to-day are frequently disappointed at the performance rendered.

Unfortunately, there is no established rules by which body builders can be certain that a specified roof camber and size of body, used with a specified solid roof material, will be soundproof. This is partly due to variations in the performance of different makes of chassis. A chassis that is flexible or that has a frame which undergoes excessive distortion, for instance, presents a very difficult problem to the body builder. Especially is this true when the spring action is snappy. When the foundation for the body has steadiness and ease of spring movement, however, the task of the body builder is less arduous. The so-called soft roof has been brought into use because of these conditions. It is new only in the sense that imitation leather is the covering used, while the foundation is generally wood slate 5/16 in. thick and 2 in. wide. These are set on top of the bows with a space of about  $\frac{3}{8}$  in. between them.

Leather roofs have been used by many high-grade custom body builders from the beginning of the art. The difference between the new practice and that of the past lying chiefly in the fact that formerly the foundation was cane work with a cotton cloth back for the lower layer, when the inside was skeleton finish or woven wire between layers of cotton cloth. When the inside is

trimmed it has been customary to use wadding.

The high cost of leather, however, has rendered it adaptable only to very high class work, while the substitution of imitation leather increases the scope of the possible use of this construction. The cost of leather at sixty-five cents a square foot as against that of imitation leather at \$1.80 a square yard, means a saving of about \$25 on the material for a five-passenger sedan. The difference in construction cost is not only in the prices of the materials, but also in the fact that there is no waste in cutting imitation leather.

A saving of \$25 can be made by the use of imitation leather as compared with an all-metal roof for a five-passenger sedan; compared with agisote or a built-up wood roof, the saving would be about half as much. These cost comparisons are based on the customary method of applying imitation leather; that is, by continuing the drip moulding around the back and fasten-

Fig. 1  
Fig. 2  
Sectional views showing two methods of constructing roofs for closed cars.

ing the imitation leather to it. The comparisons would not apply in the case of the accompanying diagram, since a combination of metal and fabric is presented there. The saving possible by the substitution of imitation leather in this case would be about \$5.

The illustrations show sections of the roof of a sedan. Two methods of improving the appearance of the soft roof are indicated. By this means the combination roof is given the high-class appearance of the metal roof without the disadvantage of noise which accompanies the latter. At the same time a leak-proof roof is insured.

The less pleasing appearance of the soft roof arises from the fact that the fabric is brought over the rounded corner of the roof rail and fastened at the drip moulding. It is, therefore, made to contrast with the lustre paint finish of the panels and, as the sun, rain and dust quickly take their toll from the fabric, the contrast, which at the first was disproportionate, is constantly emphasized more strongly.

The illustration shows one way of getting the advantage of the soft roof without the shabby side line and without taking any chance of the rain leaking through. Ordinarily when the leather or fabric is stopped on the flat of the roof, a half oval moulding is used to cover the joint. Such a moulding, however, is above the level and will, therefore, prevent a natural drainage. Thus the water held back will in time seep through.

The design shown in Fig. 1 is best for economy and ease in production. The bows are assembled in the regulation way, the slat rests in a shallow roofrail rabbet and projects above sufficiently to form the necessary step for making the water shed. The illustration is self-explanatory to a large extent. The top or outer fabric is drawn over and tacked to the perpendicular edge of the slat, meeting the sheet metal at the corner. The metal finish moulding is set in lead or thick primer,

is jammed tight and is fastened with screws or barbed nails to the hardwood of the roofrail. Lead silled moulding with set-in nails will work well, however, in certain cases. It can be readily seen that no obstructions are in the way of the natural flow of the water from the top to the drip moulding.

Fig. 2 simply shows a way to carry the dividing line further back on the roof; such construction is very much more expensive in the wood shop.

## New Self-Lubricating Bearing Material

**D**EVELOPMENT of a new bearing material which is a mixture of bronze and graphite, having self-lubricating qualities has recently been announced by the General Electric Co., following successful tests under service conditions. The commercial stage was attained by this material after research extending over a period of several years.

The new material, known as Genelite, contains graphite amounting to 40 per cent by volume of the whole mass. Tests have shown a high degree of porosity, the metal being able to absorb as much as 2½ per cent by weight of oil. Fig. 1 is a piece of apparatus set up to show this feature of the material. Oil from the upper beaker is siphoned into the lower through the rod of Genelite and the woolen wick by capillary attraction in both. This characteristic is made use of in high speed applications where oil is applied to the outside of the bushing and carried through to the bearing surface by capillary attraction. Another characteristic is said to be that the bearing never seizes or freezes, or, the metals of the shaft and the bearing never flow or weld together. If a bearing sticks, owing to too close a fit, all that is necessary is to reassemble it with the proper fit, no damage being done to the shaft or bearing.

Among the self-lubricating uses for the new bearing are brake rod bushings, clutch centering bushings, throttle control, fan and pump shaft bushings, where such material saves much trouble and expense of overhauling and repair. Genelite has proved useful also for

engine main bearings, crank pin bearings and piston pin bushings which are supposed to be well lubricated at all times, but where water is likely to be excessive due to the oil losing its lubricating value from dilution by unconsumed fuel, or insufficient oil.

Genelite is made from the oxides of tin, lead and copper, composing a high-grade bronze, plus graphite, all the materials being in a finely divided state. Graphite is added in sufficient excess quantity to reduce the oxides to the metals and leave the required graphite content in the finished material. The oxides are partially reduced by heating the mixture.

The mixture, still in powdered form, is then pressed as nearly as possible to the required shape in massive metal molds. In this pressed form it will not stand much rough handling, so it is given a final bake, which sinters the metals together into a homogeneous bronze, holding the graphite uniformly distributed throughout its mass.

Figs. 2 and 3 are microphotographs of cross sections of the same piece taken on two planes intersecting at 90 deg., and show the even distribution of the graphite particles. The white spots are the bronze and the black ones the graphite. The baking serves to clamp the graphite particles securely within the mass of bronze, so they cannot be washed out or detached save by dissolving away the surrounding metal with acids.

The material has the general appearance and body of bronze, but the characteristics are different. It does not machine readily by the ordinary methods, but can easily be ground, which has been found to be the best

Figs. 2 and 3—Cross and flat sections of genelite, former showing uniform distribution of graphite. Magnified 100 times.

method of handling it in quantity. Neither has it the physical characteristics of bronze, having very low tensile strength, but withstanding high compressive strains.

When considering the relative performance of bearings, great care should be taken that all the factors entering should be given due consideration. A self-lubricating bearing should never be compared with a lubricated one, for no bearing will give as good results unlubricated as a similar bearing properly lubricated. But it is sometimes necessary, due to inaccessibility of parts or neglect on the part of the user, to install bearings that are self-lubricated.

**A** GLOSSARY of Aeronautical Terms prepared by the Technical Terms Committee of the Royal Aeronautical Society and approved by the Engineering Standards Association has been issued by direction of the Air Council, and copies can be had from H. M. Stationary Office, London. The publication embodies a schedule of aerodynamical symbols approved by the Advisory Committee for Aeronautics. Translated and adapted to the French by Flight Lieutenant Leonard F. Plugge, the Glossary forms Air Publication No. 822. This is probably the most complete and up-to-date French-English glossary of aeronautical terms published.

Fig. 1—Test to demonstrate porosity of genelite.

# Investigation Into Properties of Lubricating Oils

Report of tests made by British committee covers measurement of co-efficient of friction at various temperatures and with oils of various viscosities. Comparisons of vegetable, animal and mineral oils with and without addition of refined or deflocculated graphite are included.

A COMMITTEE on Lubricants and Lubrication appointed in March, 1917, by the British Advisory Council of the Department of Scientific and Industrial Research, has issued a lengthy report on the results of its inquiries. It was found that the work assigned to the committee could not be accomplished solely by inquiry, and permission was sought and granted to make certain experiments.

The worm gear testing machine designed by F. W. Lanchester, and presented to the National Physical Laboratory by the Daimler Motor Co. was used to determine the lubricating properties of various mineral, animal and vegetable oils. This machine can measure the efficiency with which power is transmitted through it with an accuracy of 0.2 per cent. The method employed is the direct measurement of the ratio of the torque in the worm wheel shaft to the torque in the worm shaft. The loss of power is thus directly measured, and is not deduced as the difference of two large observed quantities. Means are provided for testing an oil on the machine over a range of temperature. It was found that for all the mineral oils tested a certain critical temperature existed beyond which the running of the gear became unsteady, and the rate of fall of efficiency with rise of temperature showed a marked increase. Animal and vegetable oils did not exhibit a critical temperature at least up to 75 deg. C. (167 deg. Fahr.) Castor oil gave the highest efficiency under the particular load employed during the tests, namely, 95.6 per cent. The efficiency of the gear with castor oil as the lubricant remained constant at this value at all temperatures from 30 deg. C. (86 deg. Fahr.) upward. Rape and trotter oil came next in order of merit to castor oil, the efficiency being practically constant at 95 per cent for both these oils. Sperm oil at normal temperatures gave an efficiency as high as any of the other oils tested, but as the temperature was raised the efficiency with this oil decreased gradually. The critical temperature shown by all the mineral oils tested was raised by the addition of rape oil, but the addition resulted in very little improvement in the efficiency figure. It was noted that the beneficial effect on the critical temperature could be produced by the addition of 2½ per cent of rape oil, and that any farther increase up to 20 per cent was without effect.

The addition of colloidal graphite to the oils under test was examined for effect. In the case of animal and vegetable oils, colloidal graphite—"Oildag," to give it its trade name—had a beneficial effect, but the improvement, according to the report, "was so small as to be hardly appreciable." With mineral oils, beneficial results were found in four out of five samples. The fifth sample showed no benefit from the addition of col-

loidal graphite. The addition of natural flaked graphite of great purity was also examined. Animal oils showed an appreciable improvement in the efficiency, no change was detected in vegetable oils, while for mineral oils two samples were improved and two left unaffected. In no case did the addition result in a reduction of efficiency, but there was evidence that the wear on the gear was increased by the presence of the flaked graphite.

The Lanchester gear tests, combined with the results of viscosity tests for the oils used, failed to provide any evidence for the assumption that the frictional resistance of the gear is dependent solely on the viscosity of the oil. Thus the viscosity of castor oil at 40 deg. C. (104 deg. Fahr.) is about six times as great as that of trotter oil, yet the frictional resistance of the gear was roughly the same in both cases.

## Viscosity and Pressure

As no tests appeared to have been carried out to determine how the viscosity of oil varied as the pressure was increased, special apparatus was designed to permit the viscosity to be measured at all pressures ranging from atmospheric up to 10 tons per square inch. It was found that at high pressures all the oils showed a very large increase in the co-efficient of viscosity. Thus at a pressure of 6.5 tons per square inch one mineral oil showed a co-efficient twenty-five times as great as that found for it under atmospheric pressure. This increase was the maximum noted. At the same pressure the increase in the co-efficient for castor and trotter oils was only 4 to 1. In general, mineral oils revealed a greater susceptibility to pressure than animal or vegetable oils. The viscosity determined was the kinematic viscosity, that is, the ratio of viscosity to density. Apparatus was designed to determine how the density of the oils varied under pressure, so that the true relation between pressure and ordinary viscosity might be deduced. It was found that the correction for varying density was not large, and that the conclusions previously reached held good.

## The Deeley Oil-Testing Apparatus

A machine designed by R. M. Deeley was constructed to enable the static and low-speed kinetic friction between flat metallic surfaces to be measured when the surfaces were dry or partially or fully lubricated with various lubricants and under various loads. Preliminary tests only have so far been carried out with this machine. It has been found that the static co-efficient of friction differs when the two surfaces are of different metals, although the lubricant is the same and also when the surfaces are the same and the lubricant is different. The results are held to indicate that "oiliness"

is a surface effect produced by the lubricant upon the metallic surface with which it is in contact. A consideration of the latest results obtained with the machine suggests, the report says, that there is a possibility of obtaining satisfactory lubrication between plain parallel surfaces without the use of tilting devices as in the Michell blocks.

Three oils were tested for the Air Ministry in the Lancaster worm gear. The first, "Mobiloil A," showed an efficiency of 95.5 per cent practically constant at temperatures up to 50 deg. C. (122 deg. Fahr.). Thereafter the efficiency fell off rapidly as the temperature was raised. The second, "Mobiloil B B," gave a constant efficiency of 94.8 per cent at temperatures below 60 deg. C. (140 deg. Fahr.), while at higher temperatures the efficiency fell off at the same rate as for the first oil. The third oil was castor oil, according to the report. In this case the efficiency fell off gradually as the temperature rose, being 96.5 per cent at 31 deg. C. (88 deg. Fahr.), 96 per cent at 35 deg. and 95.5 per cent at 100 deg. C. (212 deg. Fahr.). In a previous section of the report, as we have recorded, it is stated that castor oil showed a constant efficiency of 95.6 per cent at all temperatures from 30 deg. upward. The discordance of these two sets of results may perhaps be explained on the supposition that a misprint has occurred in the report, "castor oil" in the case of the third oil tested for the Air Ministry having been printed instead of the somewhat similar name of a well-known proprietary brand of lubricating oil.

#### Cavitation in Oil Films

At a Royal Institution lecture by S. Skinner on experiments in the liquid state, experiments were performed showing the formation of cavities in oil films when the oil was introduced between a pair of lenses or between a lens and a plane and when the lenses were rolled or rocked above a certain critical speed. These results were brought to the committee's notice, and were farther investigated at the National Physical Laboratory by means of a half-bearing of glass carrying a load and supported on a steel shaft  $1\frac{3}{4}$  in. in diameter. In this way it was possible to study the flow of oil over a simple journal bearing both during the first

revolution of the shaft and subsequently. The results obtained are believed to afford "a reliable indication of the general action of a lubricant in a bearing." The film was found to be ruptured on both sides of the line of nearest approach, and in general the facts observed confirm Mr. Skinner's observations.

#### "Oildag" in Aero-Engines

The results of some tests carried out by the Air Ministry on the degree of benefit to be derived from adding "oildag" to the lubricating oil used in aero-engines were communicated to the committee, and are published in its report. In one case, evidence was obtained that the use of "oildag" may lead to reduced oil and fuel consumption per brake horsepower hour. In two trials, however, it was made clear that greater carbonization in the cylinders was to be expected when "oildag" was used. In one instance, the consumption obtained with "oildag" was above rather than below the normal consumption without "oildag." The results generally, it is added, were not conclusive, and it was considered that farther trials were needed in order to make it possible to say with certainty whether the differences in oil and fuel consumption with and without "oildag" were due to engine design or to the type of lubricant.

Some tests were carried out at the National Physical Laboratory with the object of determining the frictional coefficient of a shaft bearing using oil with and without "oildag." The apparatus used consisted of two self-oiling plunger blocks, in which a shaft was rotated by an electric motor, the plunger blocks being attached to a frame work which could be loaded and the coefficient of friction determined by torque measurement. Two kinds of oil were tested with and without "oildag." With the first oil the addition of "oildag" resulted in a reduction of about 11 per cent in the coefficient of friction at 60 deg. C. (140 deg. Fahr.). With the second—a thinner—oil, the coefficient "was actually higher with the addition of 'oildag' than without it." This test, the report adds, was carefully repeated, and confirmed at a subsequent date.

Copies of the Report of the Lubricants and Lubrication Inquiry committee may be had from H. M. Stationary Office, Kingsway, W. C., 2, London.

## Influence of Various Fuels on Engine Performance

(Continued from page 13)

chamber, the speed and many other variables.

In Fig. 13 curve (A) shows the variation in mean pressure with compression which might be expected if the efficiency relative to the air cycle remained constant at all compressions. Curve (B) shows the mean pressure which would be obtained if the efficiency bore a constant relation to Tizard and Pye's ideal efficiency.

Curve (C) shows the relation between the mean pressure and compression ratio actually observed.

This relation, which could be obtained with a high degree of accuracy, did not vary measurably as between numerous tests on any one fuel or on several different fuels.

That the mean pressure developed does not follow either the air-cycle standard or Tizard and Pye's calculated values is explained by the fact that the volumetric efficiency falls as the compression ratio is increased. Why it should fall still remains a mystery. Many theories have been advanced, some of which, no doubt, go some way toward explaining the change in volumetric efficiency, but none can, in the writer's opinion, explain the existence of so large a variation.

It will be shown later, when dealing with the question

of efficiency, that the actual observed efficiency rose in relation to the air cycle, while the mean pressure fell in relation to it—a somewhat surprising phenomenon, in view of the fact that, so far as any change in the efficiency of the combustion chamber was concerned, it must have decreased with increase of compression, though every endeavor was made to reduce this variable to the lowest possible limit.

Fig. 14 shows in full line the observed percentage increase or decrease in mean effective pressure, taking as basis a compression ratio of 5:1. The dotted line shows what would be this relation if the i.m.e.p. were proportional to the air-cycle standard. The full-line curve may be taken as applicable to all fuels or combinations of fuels without distinction or qualification. To apply it, it is necessary only to refer to Table VIII, Column L, which gives the highest safe compression ratio at which the fuel may be used, and to add or subtract the necessary percentage observed. Table VIII, Column M, shows the mean effective pressure actually observed with each fuel at 1500 r.p.m. when run at the highest compression ratio consistent with freedom from detonation.

# Hand Work Important Factor of Storage Battery Manufacture

Engineers are interested in the production methods used in plants from which they order equipment. This article describes the chief features of storage battery manufacture in a typical plant. Economy of movement is an important feature of the process discussed here. Over 100 operations are performed every hour throughout the production system.

By J. Edward Schipper

**T**HE manufacture of storage batteries in a plant having a capacity of 1000 per day offers an excellent opportunity for motion study. The nature of the work is such that machinery is used to only a limited amount, the majority of the work being bench work or hand work of various kinds.

The Ray Battery Co., which has recently moved to Ypsilanti, has increased its production from 300 batteries a day to 1000 a day, and has found that in the production of this quantity it is necessary to make a very close study of economy of movement in the men employed in order to bring the unit cost per battery down to the proper basis. The plant operates on a 9-hr. day, which means that throughout the entire production system a capacity of somewhat over 100 completed operations per hour must be reached.

## Casting Lead Grids

The primary operation is the casting of the lead grids. This, as well as all of the operations throughout the plant in which it is practicable, is a piecework operation. The plant equipment consists of nine molds of the type shown in Fig. 1. A good operator can mold 200 of these lead grids per hour, and, as will be noticed from the illustration, the movements of the operator's hands are very limited, indeed, in order to fulfill his work. The molten lead is adjacent to his right hand, and with the left hand he operates the mold, which is a special design worked out by the Ray battery production men. A movement of the right hand scoops up sufficient lead in the measuring ladle to just fill the mold. This is poured and practically instantaneously the lead is cooled sufficiently to be hard. The mold is then opened and the finished grids taken out and placed upon the pile at the operator's left hand.

The interesting feature of this operation is the small amount of movement necessary to do the work. Practically no body movement at all is required, simply action by the left and right hands and arms. Following the operation of casting the grid, it is necessary to clean it up and trim it. This is done on a Michigan press, which shears off the excess metal, as shown in Fig. 2. This is an ordinary type of punch press, and the work of trimming these grids is also a piecework operation.

After the punch press operation, the grids are ready to receive the paste, which issues from a bin through an opening in the wall of the secret mixing chamber. As a great deal of the efficiency of the Ray battery is wrapped up in the use of the particular paste formula

employed, every effort has been made to keep the knowledge of the ingredients of this paste confined to one or two members of the Ray battery staff. An unusual feature of the battery is that the same paste exactly is used for both negative and positive plates.

The operation of pasting up the grid is similar to any other grid pasting operation with other batteries. It is done by means of a putty knife, and skillful operators will average 175 grids per hour. There is no distinction between the negative and positive plates on this filling operation. The grids are then dried, an operation which takes about 12 hr. at 120 deg. Fahr. The grids are inserted in drying racks, as shown in Fig. 4, preparatory to being placed in the oven, where the drying temperature is maintained. This operation follows directly after the hand pasting described.

After the plates have been withdrawn from the drying oven they are put through a chemical forming process, which differs materially from usual manufacture and by nature of which the time required for the manufacture of the battery is materially shortened. The usual time for battery manufacture is 14 days. By the chemical forming process employed by the Ray Battery Co. this time has been shortened to 8 days, which, of course, considerably decreases the amount of work in process at any given period and consequently makes the operation of battery manufacture that much more economical. The ability to use the chemical process is claimed by the Ray company to be due to the use of the Lavere paste formula employed in the plates.

## Trimming Lugs

After this chemical forming step is completed, the lugs are trimmed off the plates and they are then mounted in assembly racks. The plates are assembled in groups, as shown in Fig. 6. This is done in special racks which permit of fitting and burning in the same rack. Fig. 7 shows the operation of burning straps onto the plates. After the soldering is completed, the plates are matched in negative and positive groups and the separators inserted. This is also a hand operation, as shown in Fig. 8. The plate group is then ready for insertion in the jar, where it gets its bath of electrolyte and is put on the first cycle of charge.

These jars or cells are carried by trucks to the charging stands, where the batteries are placed on charge, being put through the several cycles. The charging racks call for 60 batteries in a row, and the trucks are so matched up with the platforms upon which the cells

1—Moulding lead grids. A piece-work operation which averages 200 per hr. from each mould. 2—Trimming of grids in ordinary punch press. A piece-work operation. 3—The paste comes out of the mixing room in periodical batches through the trap door shown. From here a distributor carries it to the pasters. 4—Filling grids with paste. A hand operation on a piece-work basis which averages 175 per hr. per man. 5—Inserting plates in drying racks preparatory to furnace drying at a temperature of 110 deg. This operation follows directly upon the hand pasting. 6—Assembly of straps and plates done in special racks which permit of fitting and burning in the same rack. 7—Burning straps onto plates. 8—Male and female plate assemblies are joined and separators inserted as shown here. The group is then ready for insertion in the jar, where it gets its bath of electrolyte and is put on the first cycle of charge

9—Method of handling groups of cells in the various processes of charge. 10—After cells have gone through their various charging cycles they are dropped into the boxes and trucked to the compound department. 11—Burning on connectors. From here the battery goes to final inspection and paint dress-up, thence to the shipping-room. 12—Compound is poured, after which the battery progresses down the bench to the connector burning process.

rest that they can readily remove a group of cells and place them in the desired position with a minimum of effort. This truck operation is shown in Fig. 9. The method of raising the platform of the truck to carry the cells is shown.

The cells are lifted from the charging stands directly into the boxes which are on a platform on the same level as the cells, so that the operator has no carrying of any consequence to do. He simply reaches over to the charging stand and lifts up the jar from one side and places it on the other side in the boxes. After the cells have been dropped into the boxes, they are taken by the trucks to the sealing department, where tar is poured around the jars, thus sealing the batteries in the battery boxes. The connectors are then burned on and the batteries are finished, painted, inspected and the plugs put in.

**T**O eliminate entirely the question of "feel" in micrometering, Rudge-Whitworth have patented a combination of an ordinary micrometer with a spring balance. The latter has a dial gage, similar to those used for weighing letters, and the micrometer is mounted in the place of the usual scale pan. The micrometer having been set, the article to be measured is passed downward between the measuring faces, and the friction of its passage is indicated on the dial of the spring balance. A difference in size of only one hundred-thousandth of an inch is detectable by this method. For the measurement of gages the "Millimike," as the device is called, should be particularly useful. For setting the micrometer to known dimensions, hardened steel balls up to  $1\frac{1}{4}$ -inch diameter are supplied, which are certified accurate to size within the limits of possible measurement.

# Factors of Territorial Analysis

Marketing has not undergone the close analysis to which production has been subjected. Its problems are less tangible and many human and psychological factors are involved. Analysis must determine the unknown factors and their relation to each other. This article discusses one phase of the problem which is important to practically every sales department.

By Norman G. Shidle

**T**HE shotgun method of selling cars has had its day. Scattering fire of sales effort cannot stand up under the close scrutiny of expenses which must now be directed by the management on every part of the business. The problem of correlating production with sales has become a live one for the first time in years.

Conditions and ideas will differ in various plants. One automobile manufacturer who has been specially successful in selling during this period of business depression takes the attitude that the production department is supreme, and that it is the function of the sales department to sell the cars necessary to keep the production facilities operating efficiently at all times.

In other plants the sales department is the dominating factor. The sales manager determines to the best of his ability how many cars he can dispose of during a coming period, and the production department is expected to adjust itself to the conditions imposed by the sales department. Just at present it is not difficult for the production department in any plant to accomplish this, but conditions were very different a year ago. In any case, the relationship between the production and selling departments and the proper correlation of the activities of the two constitutes an important problem; a problem which is found to be solved differently in different plants.

The necessity has arisen for some sort of accurate territorial analysis, some reasonable standards upon which to judge performance and some fairly accurate method of predicting future performance.

The purpose of such an analysis may be for the purpose of determining the capacity of a plant about to be built, or for determining where the capacity of an existing plant may be sold. The latter is the commonest purpose, but in either case the methods of analysis may proceed along similar lines.

To establish a quota for any given territory is easy; to establish a fair and accurate one is very difficult. An inaccurate quota is worse, of course, than no quota at all. Inaccurate standards of performance simply warp the entire view of the performance itself.

In discussing quota and territorial analysis, the term quota needs to be defined. In some cases quota is considered as being the share of plant capacity which shall

go to a given unit. This relation is relative, however, and to be determined accurately must rest upon a more fundamental analysis. It is the result of such an analysis that constitutes the true quota, as the term is used in this article. Quota is the number of cars that a given territory is capable of absorbing. In other words, a territorial analysis aims at determining the maximum market for cars in a given territory. Once this has been done, it is simple to adjust the relative values in apportioning factory output or in setting actual performance quotas for dealers in such a way that they are suitable for practical use. The analysis on an absolute basis is the scientific foundation, however, for the other type and constitutes the basis of the present discussion.

A few companies have recognized the necessity for effort of this kind and have done considerable work along this line. These efforts have already paid for themselves and have greatly aided in selling through the present difficult period. It is interesting to note that at least two companies which have done the most work in regard to territorial analysis and the establishment of accurate quotas have weathered the recent industrial storm better than most others and, with increased ef-

forts, have made their 1921 sales equal or surpass those of 1920 for corresponding months.

## Two Main Phases

There are two phases of sales analysis from the standpoint of the manufacturer. The factors to be considered must first be determined. Then their relative importance in relation to one another must be established in order to properly evaluate any given territory. To accomplish both of these things to the highest degree of mathematical accuracy is manifestly impossible. To accomplish them to a greater extent than has heretofore been done is not only possible, but necessary. The more careful the analysis and the more intelligent the study, the more accurate and valuable will be final results.

This article proposes to discuss these two phases in a purely qualitative way, with the idea of indicating the various factors involved and the things which affect their relative importance in a study.

The first factor of territorial analysis for passenger cars is likely to be population. Population may be said to indicate the total number of persons who might ride

---

**B**EFORE a territory can be analyzed a proper territory must be defined. A sales territory cannot be intelligently designated by simply using a map. Spheres of city influence, newspaper circulation, arterial roads, local buying habits and other factors enter into determining "when a territory is not a territory" and vice versa. This is a preliminary to the factors discussed in this article.

---

in cars. It does not indicate directly, of course, the actual market for cars. Indirectly, it has a definite bearing, however, since, other things being equal, the place with the largest population offers the largest market. Since other things are not always equal, however, the market in two territories will not necessarily be in direct proportion to the population.

It may be said, then, that population is a factor in every sales analysis, but that it must be correlated with other special factors in any given case in order to be accorded its proper significance.

Closely allied with the actual population factor is the number of persons per car. Under present conditions the importance given to this factor should be carefully considered. In many states it is impossible to get this figure with any degree of accuracy, because car and truck registrations are not segregated. Moreover, the conditions of territories in various parts of the country differ so greatly as to render this factor of varying importance in different places.

The total car registration for the territory constitutes another factor. Here, again, difficulty is experienced when cars and trucks are not segregated. In addition to the total registration, however, other more detailed factors must be considered. The number of Sennett cars in the territory should comprise a factor in an analysis made by the Sennett factory. One factory, for instance, has already in operation a system by means of which they can determine by reference to a factory file the territory and ownership of every one of its cars.

Then the number of competitive cars in the territory should be taken into account. The data can be obtained by some expenditure of money for lists. This factor is equally as important as that of the number of Sennett cars. It indicates not only the sales performance of the Sennett dealer and the competitive dealers, but also the possible market in an indirect way.

The model as well as the number of Sennett and competitive cars in a territory should be known. With this data the approximate number of replacements can be calculated each year. This will also have some bearing upon the used-car market and the relation which it bears to sales resistance. In this connection, the replacement possibilities in cars of a class lower than the Sennett might be considered. For this purpose the same data should be available on cars of this lower class as for Sennett and competitive cars.

#### Financial Factors

The factors having to do with actual buying power are of supreme importance. To determine them accurately and to correlate them properly constitutes probably the most difficult part of the sales analysis task.

Income tax returns offer one obvious source of data. Certain information can undoubtedly be obtained from this source. Men in certain income classes may be considered prospects for Sennett cars. This factor should be considered as exclusive, however, rather than inclusive. Suppose, for instance, that persons with an income between \$2500 and \$5000 are considered as Sennett prospects. All those showing such incomes on the income tax returns can be properly considered as prospects. But that number is by no means the limit of the number of prospects in that territory.

There is a farmer up in New York State who earns about \$500 a year. He is employed by the owner of the farm and has no outside resources or income. He has a wife and three children. This man will never appear in the income tax returns. Yet he has owned a car for over three years. And this case is not exceptional. The income tax returns do indicate certain things about

sales markets, but they must be considered in relation to other factors or they give false impressions. The vast number of persons who must own a car for business purposes, regardless of their status as regards income taxes, give another excellent example of the fault of laying too much importance upon this single factor by itself.

Property values constitute another possible factor. These, too, must be carefully considered in their relation to other factors. Property values are, in a sense, a measure of the community wealth, yet they may be a very false measure. It is the distribution of property that counts in automobile sales, not the total value. There is a small manufacturing town in Pennsylvania, for instance, where nearly the whole town is owned by the head of the one large factory. There are few high-salaried men in the town. The market for cars is comparatively small, yet the property values would show a considerable total.

It must be remembered that high property values usually reflect high rents, which in turn act as an increased sales resistant. The distribution of the property, the number of persons who own their own homes, as against the number who pay rent, these are the factors of importance, rather than mere property value.

Financial ratings are also a factor in selling cars, especially for business purposes. They are not as large a factor, however, as in selling trucks. Factory wages, as well as income tax returns, might form a factor in certain instances.

#### Economic and Local Factors

There are certain local economic factors which will influence the market in any given territory. The matter of garage facilities is one. Here, again, the limitations of the income tax factor are illustrated. In a territory where most car owners have to pay from \$20 to \$35 a month for housing their car, the sales resistance will be very much greater than one in which most users can house their vehicle in a private garage for a very small sum.

Local topographical conditions may influence the sale of a particular car in certain localities, while current business and economic conditions are certain to have an effect. Whether the territory is urban, suburban or rural is a factor in making or reducing sales resistance and, consequently, is a factor in properly evaluating a given territory.

These factors are intangible, and, unlike most of the others mentioned, can be reduced to a place in a formula only with considerable difficulty. Since they are present factors, however, they should be taken into consideration along with the rest of the problem.

#### The Human Side

The human and psychological factors which enter into the value of a given territory are also of immense importance. So little is known about this phase of the question at present, however, that it can be discussed only briefly in a short article. The community likes and dislikes, the intangible whims of the public in a given area, the psychological factors which enter into merchandising, all these things must have a part in the ultimate determination of accurate territorial valuation.

Why do people in New York prefer white eggs, while Boston housewives are willing to pay a higher price for brown eggs? Such a question as this cannot be answered on the basis of economics. It has to do with the psychological phase of merchandising. Discussing this point in his book, "The New Business," Harry Tipper says:

"That the older methods of marketing and the older methods of doing business are inadequate to the present-day situation is obvious, both from the history of commerce and a study of present friction and unrest.

"What changes will be effected it is difficult to say, and much investigation and analysis are necessary before any direct statement as to changes would be of value. Certainly not until analysis has determined a good deal more effectually the unknown factors which enter into marketing would it be other than absurd to talk of much change.

"As the analysis, however, develops some of these factors, it is probable that the new spirit of marketing will become a factor in business in the same way that the new methods of production have dominated the manufacturing."

The factors mentioned comprise the chief things to be considered when attempting to thoroughly analyze a territory from the manufacturer's viewpoint. For greater clearness they may be listed in tabular form:

1. Population.
2. Number of persons per car.
3. Total registrations.
4. Number of Sennett cars in territory.
5. Number of competitive cars in territory.
6. Number of next lower price class in territory; in case of some cars, number of people who own more expensive cars in territory.
7. Model (year) of Sennett cars in territory.
8. Model (year) of competitive cars in territory.
9. Model (year) of next lower price class in territory.
10. Income tax returns.
11. Property values.
12. Distribution of property.
13. Financial ratings.
14. Current factory wages.
15. Local economic conditions.
16. Local business conditions.
17. Local topographical conditions.
18. Human and psychological factors.
19. Factory production capacity.

The importance of each of these factors will be different in the case of each different type of car. Some of the factors will be practically negligible in connection

with certain makes and important in connection with certain others.

To determine the relative importance of each factor, to determine the relation of each factor to each other factor; to correlate the data obtained concerning each of the factors—this is the second phase of territorial analysis. It is the most difficult phase. Perhaps sufficient data are not available on the basis of present records to successfully complete the second part of the task. Perhaps more study and analysis of the various factors will be necessary before definite progress can be made in this direction.

It is altogether likely that this is the case. One automobile company, which has gone into this matter more extensively than most others, has devised a formula for territory valuation which it is using at the present time. This formula is different than the one used six months ago, and is likely to be changed again within the next six months.

The factors outlined here merely present a basis upon which territorial analysis for car sales may proceed. The problem of the individual sales manager is to build his own analysis on the basis of these factors and to determine for his particular car the relationship between the various units involved. Some progress can be made immediately in most cases. The field has been little studied, and experimental data is comparatively meager.

It is perfectly possible that experience will show that it is not feasible to establish a standard quota formula which will be good forever, even for a particular car. The relative importance of the various factors may be found to vary from year to year and from territory to territory. It may be necessary to constantly adjust the territory valuation. But if this is found to be necessary, the sales manager of the future will be able to make that adjustment upon the basis of accurate data and intelligent analysis. The factor of error will be reduced to a minimum.

It is not likely that the description of the working out of the second part of this analysis task can be written in the near future. But experiments can be made which will furnish quantitative data upon which to base further progress. This is the present problem of the merchandising departments.

## Output of Single and Multi-Cylinder Engines

A TEST was recently conducted at McCook Field on a single Liberty cylinder mounted on a universal base to determine the power, friction losses, temperature and heat transfer characteristics. This performance was compared with the average of eight standard 12 cylinder Liberty engines in order to obtain a factor which would indicate relation of its performance as a unit of a multi-cylinder engine. This factor was desired in order to make it possible to predict the performance of new multi-cylinder engines from single cylinder tests.

A low mechanical efficiency was obtained, probably due to the fact that two magnetos, regular oil and water pumps, regular cam-shaft drive, and a heavy flywheel were driven by this cylinder. The power required to drive these accessories is usually distributed among a multiplicity of cylinders. However, the effect of low mechanical efficiency on the power output was apparently balanced by an increase in the volumetric efficiency due to the single intake pipe, since the indicated power output was considerably greater than one-twelfth of that which is usually

obtained from a 12-cylinder Liberty engine. Due probably to the increase in volumetric efficiency, the brake mean effective pressure curves do not drop off so fast, and the power curve peaks at a higher engine speed than with the standard Liberty engine.

Apparently an accurate estimate of the power of a multi-cylinder engine can be made by taking the brake horsepower developed by a single cylinder on the universal engine as the average performance of similar cylinders in a multi-cylinder engine.

TECHNICAL Note No. 48, dealing with Airplane Superchargers, a translation of an article by W. G. Noack in the Zeitschrift des Vereines deutscher Ingenieure has been issued by the National Advisory Committee for Aeronautics. The note is in multigraph form, and we believe that the Committee, whose address is Washington, D. C., have a few copies for distribution to interested parties.

# When the Factory Assumes the Service Burden

The reputation of a vehicle depends largely upon the way in which it is serviced. Few service stations have been free of criticism during recent years. A factory service executive, who has had troubles in the past, tells how difficulties have been overcome by his organization.

By H. N. Davock\*

IT is probably safe to say that at least half the reputation of a motor car or truck rests upon the repair service that maintains and insures its good condition for continued use. No matter how perfect the design and workmanship of a vehicle, it cannot and will not stand up long unless it is kept in first class condition by systematic inspection and adjustment. But even a very second rate vehicle can be kept going a long time beyond its normal life if well serviced. Moreover, owners of high-grade vehicles will quickly become dissatisfied, and quite justly so, if they find difficulty, delay, or excessive cost in keeping their cars or trucks in smooth running order while conversely a good running Ford hitting in all four will make its owner far happier than a noisy, rough and poorly conditioned car of higher grade which limps along with a cylinder missing.

The automobile industry as a whole has been too slow in recognizing this situation and I must include our own company in the indictment in spite of the fact that it has from the first paid very considerable attention to the matter of service. Far too often owners of vehicles have felt that neither their treatment at the service station, the work that was done there, nor the price that was charged for it were fair and businesslike. Mostly this has been due to the practices of fly-by-night service stations and garages that sprang up all over the country. They charged all the traffic would bear and they operated by methods little less than sheer robbery.

But in the unsettled condition of the automobile industry in the last few years there have been few service stations indeed that have been free from criticism. As a result there were complaints from customers that added very materially to the difficulty of making new sales. Not all of these complaints were justified, but their effect was the same whether they were fair or not.

Because of this situation the Packard Motor Car Co. about three years ago undertook a very careful study of its service stations and of the complaints that were made there. As a result it has evolved a system that has not only very materially reduced the number and volume of complaints, but has also proved of distinct service in insuring reasonable charges on repair operations in these stations. Incidentally, in many cases it has put losing stations on a profitable basis.

As the foundation for our study we worked out a list of complaints in the order of their number and importance and by careful consideration set down for each one the methods of correction which have been undertaken.

These two lists are as follows:

## Customers' Complaints and Their Correction

<i>Complaint</i>	<i>Correction</i>
1—Work not done on time.	1—Definite scheduling system in the shop. Definite knowledge of actual time required for proposed job. Close co-operation between service office and shop regarding deliveries.
2—Work not done as desired.	2—Analysis of customers' complaints. Definite explanation by service salesmen. Definite instructions to shop for work. Definite inspection system. Supplementary orders to be issued when required.
3—Work not done properly.	3—All work on definite schedule. Inspection system in the shop to insure correct work. Education of mechanics. Special tools and time study. Thorough final inspection.
4—Charge for work more than expected.	4—Work estimated in advance. Customers sold on the necessity of all repair orders and supplementaries. Customers supplied copy of repair orders, showing estimate.
5—Charge for work excessive.	5—Customer given to understand exact nature of work. Definite estimates of expense available at all times. Equitable system of setting labor rates. Elimination of red tape, and economy throughout establishment.
6—Charge for work which should be no charge policy.	6—Service salesmen and inspectors thoroughly familiar with Packard warranty and service policies. Definite explanation to customer with regard to charge in advance. Good service salesmanship.
7—Error or delay in billing.	7—Continuous summarizing of time and material during progress of the repair. Careful check-up on completion of work. Safeguards on time and requisitions summary.
8—Discourteous, dilatory or delayed attention to customers.	8—Spirit of Packard service instilled into every employee. Morale maintained by adequate compensation, discipline and organization. Proper facilities for entertaining customers. Proper scheduling of repair jobs.

\*Manager Technical Service Department, Packard Motor Car Co.

It will be seen from these lists that the complaints and their corrections occur at three distinct stages of the customers' relations with the service employees. The first is in the matter of personal relations in the approach and understanding between employees and the customers. The second is over delay or failure to live up to definite promises. The third, often a natural consequence of the other two, has to do with the feeling that the cost of the work has been excessive. Of course, all three interlock and it is often found that a reform aimed at any one of these difficulties improves the situation in regard to the other two.

The most important factor in working out the answer to this problem was standardizing the system of handling service work, but there have been some general measures in our service work that are proving of great value. The first of these and the most vital has to do with the personnel of the organization. It was evident that a very large proportion of the complaints occurred because the customer had not been properly sold either on the need of the repair work that was done or on the fairness of the charge for the work. To faulty personnel also could be traced all complaints of discourtesy and many of the complaints of delay. The successful repair or adjustment of the vehicle is only half of the job of the service department, the other half is in keeping the customer's mental attitude right. It is entirely possible to send a customer away dissatisfied even though the actual repair work has been done promptly, properly and at a reasonable cost.

### Selling Service

The job of the salesman is to sell service, but he is also to make sure that the customer departs with that mental satisfaction which we consider standard equipment with all of our vehicles.

Of course, satisfaction cannot be sold. It has to be earned. The service salesman's job is to see that the service station does earn that satisfaction, and that the customer knows that the service is so fair and business-like as to entitle the station to his good will. For this reason the service salesman must be an exceptional man, of good appearance, speech and all the other qualities of first class salesmanship; he must also be thoroughly familiar with Packard service policies and routine and he must not be so clever that anyone will have a doubt of his absolute squareness. Most important of all he must be the type of man who quickly makes a good impression that is lasting. He will be in touch with the owner of a vehicle throughout its life, whereas the car or truck salesman will be in touch with the man only during the brief time required in consummating the sale.

One of his particular duties is to educate the customer

in regard to the cost of maintenance and repairs. Very few people have any idea of what it is actually worth to make any standard repair on a vehicle. We make it a matter of policy to see that our owners are conducted through the service stations and are given an opportunity to learn just how and why the charges are fixed on any given job. We have found that this was one of the most important of all measures in cultivating a customer's satisfaction.

### Adequate Parts Supplies

The second general matter, which has to do chiefly with efficiency and speed, is in insuring an adequate supply of parts for repairs at all times, in all places, and for all vehicles that Packard has ever manufactured. This is a very considerable task, inasmuch as there are Packard vehicles well over 15 years old which are still in service and quite naturally these vehicles are likely to be among those that most frequently come in for repair.

The system of providing adequate parts supply begins at the factory. We have what we believe is the only separate factory in the country devoted to manufacturing service parts. In it we have every jig, tool and fixture necessary for turning out any part of any vehicle that we have ever manufactured. We make it a point, also, to keep on hand at the service factory complete inventories of all these parts and it is our boast that we are able to fill 98 per cent of all orders on the day they are received.

In furtherance of this policy of insuring adequate supply of parts, depots have been established at various points in the country, where full inventories of all parts commonly demanded are kept. So distributors and branches who run short or have unexpected demands need not wait to get their supplies

from the factory in Detroit.

Every Packard distributor is under contract to keep on hand an assortment of replacement parts varying in size from \$1000 for very small sub-stations to \$300,000 for our metropolitan plants in the larger cities. The Technical Service Department at the factory furnishes an accurately proportioned selection of repair parts for all the organizations. The extent to which this is carried was illustrated by a recent test made in the case of the Montreal distributor. Without notice a demand was suddenly made on his stock room for a total of 599 different service parts. The stock clerk was able to supply 598 parts.

### Prices

The third general policy has to do with prices. We spent some time in trying a flat rate system of charges, but found it generally unsatisfactory, and for about

Monthly or 1000 miles. ORIGINAL—Service File 1

Service Salesman

- 1 If while above work is being performed additional work is found to be required, this Company will endeavor to secure customer's approval for extra expense and time involved.
- 2 This company is not liable for loss or damage to vehicle by fire, theft, casualty or accident and the vehicle is held at owner's risk.
- 3 Except as noted herein parts removed for renewal will be scrapped at once.
- 4 Storage will be charged at \$..... per day, beginning 48 hours after notice of completion of order.
- 5 All estimates are subject to immediate acceptance.
- 6 No claims will be considered unless presented within 60 (10) days.

I hereby authorize above order and agree to terms specified.

two years now have been using a system of maximum estimates. According to this method the customer receives a maximum estimate on the work to be done, with the assurance that the price will not run beyond this estimate. As the job passes through the shops careful cost accounting is done on both labor and material. If the figure thus arrived at is less than the estimate quoted, the customer is billed for the actual cost. If the work is more than estimated the customer is billed for the amount estimated and the service station stands the difference, the deficit being charged to overhead.

This system has created a feeling of confidence among customers that is very pleasing. It frequently results in a bill that is lower than the estimate given, which naturally has an excellent effect on the customer. As time goes on the margin of variation is being narrowed down by standardizing repair operations and equipment and there are many of the most common jobs on which we are now in a position to quote flat rates that are really equitable.

## Checking Trucks

Finally, we have carried our salesmanship service outside the service stations, especially in regard to trucks. The truck owner usually knows nothing about his truck except what is reported to him by the driver and the driver may or may not take the time and trouble necessary to keep the truck in good running condition. If he does not, the first thing that the owner knows his truck will be laid up for major repairs which would often have been unnecessary if service had been attended to at the proper time and which will certainly cause serious interruption in his business.

To meet this we have established the policy of checking up closely on our trucks, especially during the first few months after they are put in service. During this period a service field inspector is frequently sent out

by the service salesman to hop up beside the driver of a truck, sometimes take the wheel himself and make certain that the vehicle is in good condition.

## Inspection Form

A complete report of each unit is made out in our standardized service inspection form, Fig. 1, which is in duplicate. The original is for the use of the service salesman, while the copy goes to the owner. A column headed "AG," meaning "attention given," indicates the minor adjustments made by the inspector. The column "AR"—"attention required"—carries the most important data, and that about which the owner is most likely to be ignorant. A letter or a telephone message from the service salesman to him tells him just how serious the trouble is, the time necessary for repairs and the maximum cost. Arrangements can then be made for having the service given with the least possible trouble to this owner.

In this way we catch trouble in its earliest stages, keep down the total repair bills and greatly increase the satisfaction that owners feel in their vehicles. Thus the inspection service gives mutual benefits, protecting truck owners against wrong usage of their property by careless drivers and protecting our own organization against repair claims by unscrupulous drivers. In addition the company has the benefit of the customer's satisfaction which results.

The system we have worked out for handling service begins the moment the car appears in the service station. We have urged that there should be a different place for handling cars and trucks and that the two be kept separate. There is a distinct difference in the personality, the needs and the attitude of car and truck users and each can most efficiently be handled in its own way.

When a vehicle arrives the customer is waited on immediately by a service salesman and taken into a neat

Inspector

Service Salesman

and quiet office calculated to give the proper impression of the standards of the company. The salesman learns as much as possible of the customer's wishes. He is in intimate touch with the shop and advises the customer about how long the work will take and when it is the best time to bring the car in. He endeavors to make a definite promise on delivery of a job whenever circumstances permit.

If the work is of such a minor nature that it is possible to write up complete shop instructions at once and at the same time give the maximum estimate to the customer without going into details, the repair order, Fig. 2, is filled in by the service salesman. The customer signs this as a definite order for the work and receives a copy.

If it appears that some study is necessary either to determine the amount of work to be done or to fix the maximum estimate, another form, Fig. 3, is used. In a case of this kind the job is turned over to the inspector for road test and detailed inspection to ascertain just what is needed. The inspector reports back to the salesman, submitting this form filled out and the salesman then explains to the customer exactly what work is required and why it is necessary. The customer can then approve or disapprove of the order as filled out. In this manner we make certain that no work is done except on the definite order from the customer and also make certain that if necessary work is not done the customer will know that it was by his own instructions that it was omitted. Thus we eliminate two of the frequent causes of complaint; the customer will get exactly what he asks for and neither more nor less.

This form, Fig. 3, has five main functions. It is the report of the service salesman to the service inspector stating the general complaints of the owner on the vehicle; it is the inspector's report of the work he recom-

mends to be done; it is used for compiling the maximum estimate recommended by the inspector; when approved it contains all the information used in typing up the repair order; and it is filed to serve as a permanent record of negotiations and the condition of the vehicle. As already explained this form is used only when the work is extensive enough to require either a detailed inspection or estimate.

The salesman is required to have a definite understanding with the customer in regard to the terms of payment. If credit is to be given, it must be definitely understood and approval recorded on the form. Careful attention to this with tact saves a great deal of money without any loss in the customer's satisfaction.

## Delivery Promises

The salesman is not permitted to give a definite promise of the time of delivery of the car when extensive repairs are to be made, but he does estimate a time and every effort is made to meet this estimate. In making the estimate he has to consider what parts are to be used and the probable length of time required to obtain any which are not in stock, the amount of work in the shop and the general difficulty of the job. Customers can frequently be persuaded to bring their cars in for small jobs when the shop is not rushed or late in the week for work requiring several days. This matter, if handled with wisdom goes far toward keeping an even run of work through the shop with a very considerable saving of idle time.

Throughout all this part of the negotiation the salesman and inspector are particularly warned to avoid recommending any unnecessary repairs. They are instructed to show the difference between "serviceable condition" and "standard operating condition." For example, a noisy or squeaky spring is not in standard oper-

ating condition, but it is in serviceable condition. To tell an owner that a car with such a minor defect should be put in the shop for repairs would reflect on the salesman's judgment and give the customer a bad opinion of the service he is receiving from his car.

After being filled out by the inspector, the form shown in Fig. 3 is turned over to the estimating clerk for prices. This is not done in the presence of the customer, but he receives a copy of his signed order.

The cost of repair operations varies considerably in different service stations due to the variable factors, such as rent, labor costs, and so forth, and each station is urged to make up its own maximum cost estimates from its own records. Until these are available the Technical Service Department at the factory supplies tentative estimates. Where operations are not covered by the estimate book, the best judgment must be used, adding 20 or 25 per cent as a factor of safety. This is no hardship on the customer since if the work actually costs less than the estimate, he receives the full benefit of the saving.

If the order has been properly sold to the customer, the repair order, Fig. 2, a copy of which is given to the customer, is made out in triplicate. Fig. 3 is then held by the service salesman pending completion of the work.

When the repair order is filled out and the job started through the shop, a disposition tag, Fig. 4, is attached. This has three parts. The bottom part is a receipt given to the customer and when signed by him gives authority for the delivery of the vehicle to his representative. The "released" portion is turned in to the accounting department when the job is ready for delivery and it gives notice that the billing should be completed immediately. The completed portion gives information to the Service Department that the mechanical part of the transaction has been finished and the vehicle is ready for delivery. The use of tags of different colors is a silent method of informing the Service Department of the customer's financial rating; special rush jobs or other matters of that kind.

When the vehicle leaves the shop the gate man removes the completed tag, checks it with the coupon which the customer has given and returns both to the service sales office, where they are filed.

Owners frequently request that accessories and loose equipment be stored by the service salesman while the vehicle is in the shop to prevent loss. To meet this requirement we have devised form shown in Fig. 1, which lists all the equipment of the vehicle and serves as a checkout when the work is completed. It eliminates practically all disputes in regard to equipment or missing parts of the car.

When the car goes to the shop the shop-office copy of the repair order, Fig. 2, goes with it to the shop office. On the reverse of the shop office copy are found the time and requisition summaries which are filled out during the time the car is undergoing repairs. The successful operation of the system depends upon the correct use of this record.

1. It shows all time and material used on each item as the work proceeds, indicating at all times the state of completion of the job.
2. It shows whether the estimated time has been exceeded on any item and by how much. It shows what work has been completed and the amount of time and material required.

3. It provides the basis on which the cost and the charge to the customer are computed.
4. It is a detailed record of the time and material to be used in billing the job.

The form may also be used as a job setting sheet. The foremen assign men to the work in advance by the use of time slips so there need never be any time lost in transferring from one operation to another. Material is requisitioned in advance and is ready for use when needed. A standardized repair job envelope is part of the system to keep all data together as it accumulates in the shop office.

#### Procedure

Whether the job is completed in the shop and has passed final inspection, the shop office copy of the repair order is examined by the shop clerk to make sure there is no omission of time or material and is sent to the service sales office to be audited and billed.

Another copy of the repair order form, the work instruction copy, is placed in a celluloid faced envelope attached to the car and goes with it through the shop. When the repair order covers more than one sheet an envelope should be provided for each sheet. When a workman has completed a particular item on the repair order he reports to the foreman, who inspects the finished work and indicates that this job is completed by a punch mark on the item number. If there is any special information which should be brought to the attention of the service salesman on the completion of the job, the item is marked with some approved sign instead of being punched and a complete written explanation is made by the foreman in the blank space on the back.

When a job has been completed in the shop it is turned over to a final inspector who checks the work and tests the vehicle. If any work is not satisfactory he should mark "rejected" on the back of the work instructions copy with notations and instructions. If he finds work is necessary which is not covered by the original, a supplementary order is issued by the Service Sales Department. It should be noted that in no case is it permitted to bill the customer for such work unless his authorization has been secured for it.

This system is outlined here only as it affects the customer. It is backed up, of course, by a complete system of time slips, stock requisitions, requests for credit and all the usual forms to insure prompt and accurate handling of the work.

When the work on the car has been finished the inspector signs in the blank "Cleared for Delivery" on the work instruction copy of the repair order and notifies the shop office clerk who checks over the accounting on the job carefully, forwarding it to the service salesman, who again checks it. The car is delivered to the service floor and a "completed tag" is attached. If the car is to be washed and polished, this is done and the car is then set in the space provided for vehicles ready for delivery, where it will be protected from damage. The service salesman holds the necessary sheets until the customer comes to take delivery.

When the customer arrives, the service salesman makes sure that the car is ready for delivery with equipment the same as when it was brought in for repairs. The customer either pays or makes necessary arrangements at the cashier's window for the release of the car while it is being brought up. When the car is driven

# The FORUM

## In Defense of the Air-Cooled Aircraft Engine

Editor, AUTOMOTIVE INDUSTRIES:

In view of the many broad statements regarding air-cooled aircraft motors at present finding utterance in this country, it would seem that investigation of the present state of knowledge of the many personal opinions that are bluntly put forth as facts is justified.

The writer is frankly biased in favor of the air-cooled motor, but nevertheless is not so prejudiced as to be unable to grant that water-cooling has its advantages, or that air-cooling has reached the pitch of development of its water-cooled rival.

In particular at the S. A. E. Summer meeting positive statements regarding air-cooled engines were made as follows:

By L. E. Pierce and G. J. Mead—

(1) That the parasitic resistance of the air-cooled motor is considerably higher than that of the water-cooled motor.

(2) That the reduced vulnerability of the air-cooled motor is of little practical military advantage.

(3) That air-cooling at present allowed of only relatively low mean effective pressures.

(4) That air-cooling does not allow of easy temperature control.

(5) That the weight comparison of the two types is not favorable to the air-cooled motor.

By Col. J. G. Vincent—

(6) That air-cooled engines were made in the radial form for cooling reasons rather than aircraft requirements.

It is proposed to reply to these statements.

(1) Little evidence regarding relative resistance of air and water cooled units seems to exist; if it does it is by no means widely known. These notes will have achieved something if they result in bringing before airplane designers generally definite comparisons between various types of engines cooled by both systems. The only figures the writer has been able to obtain are as follows:

(a) Engine and body resistance of RE-8 with 150-hp. R.A.F.-4A engine (12-cylinder air-cooled Vee with scoop cowl)—53 lb.

(b) RE-8A with 200-hp. Hispano engine (exactly as RE-8 except for engine, engine fairing and cooling system)—66 lb.

Both of the above are from a Royal Aircraft Factory Report and are at 100 ft. per sec. and tests on one-fifth scale models.

It has been stated on good authority that model tests have shown that the resistance of an air-cooled radial engine has a somewhat higher resistance than a water-cooled eight-cylinder Vee, but on the other hand full scale tests on the Sopwith "Snipe" and Nieuport "Night-hawk" have shown over 140 m.p.h. level flying speed at 10,000 ft., this performance in the case of the former being obtained with an engine that was not giving more than 280 hp. on the ground and probably less, which would seem to indicate that the resistance cannot be much

in excess of that of a water-cooled engine of similar power.

Further it may be pointed out that the A. B. C. "Dragon-fly" engine has a relatively high resistance for the power given and that an engine of similar size and resistance with high efficiency cylinders could be built to give 400 b.hp. at sea level.

It would be of considerable interest if Messrs. Pierce and Mead would produce figures and their authority for their statements regarding relative resistance.

In view of the fact that the air-cooled motor has a considerably higher mean temperature difference between the cooling surfaces and cooling air than for the water-cooled motor (between 220 and 280 deg. Fahr. mean temperature above air is an average figure for an air-cooled cylinder running with a blast velocity giving maximum power, the mean temperature depending upon cylinder size and the blast velocity varying from about 60 m.p.h. for a 65 cu. in. cylinder to 85 m.p.h. for a 150 cu. in. cylinder) and will therefore require less air to dissipate a similar amount of heat, it would seem that there is a fair expectation that the resistance will therefore not greatly exceed that of a water-cooled motor faired with equal skill.

(2) Then with reference to the statement that the "lesser vulnerability to shot and shell is of little importance as most planes that fall come down in flames." This does not agree with the views of many pilots who flew on the Western Front; many cases are on record of machines being brought down by a single shot through the radiator or water jackets (for instance, the engine from which the first official British published data on the 160 hp. Mercedes was obtained, was put out of action by a single shot through a water jacket). Further, the connection between shots through the cooling system and going down in flames seems somewhat remote.

The British, who used the stationary air-cooled engine to a greater extent than any other belligerent in the late war, had a great respect for this type of motor on the score of reduced vulnerability.

(3) With reference to mean effective pressure, a cylinder of  $5\frac{7}{8}$  in. bore by 6 in. stroke, and of American design and manufacture, has given 120 lb. per sq. in. brake mean effective pressure (29.9 in. barometer and 60 deg. Fahr. air temperature) at 1800 r.p.m., the said cylinder being as yet relatively undeveloped. It would seem in view of the fact few water-cooled engines of such size greatly exceed the above mentioned performance at such speed, that fairly high mean effective pressures are not only a matter of report.

As enthusiasm is a primary necessity for success in most mechanical fields of investigation, it would appear unfortunate that Messrs. Mead and Pierce have no real belief in the type they criticize.

(4) With reference to temperature control, there is a good deal of doubt as to whether any real difficulty exists, provided the supply of heat to the induction system be such as to maintain reasonably constant carburetion and distribution. It is the writer's experience on air-cooled engines generally, not alone the aircraft motor, that it is possible to operate over a range of as much as 350 deg.

Fahr. variation in maximum cylinder temperature without any relatively large variation in motor performance.

(5) With regard to weight comparisons, while the writer hesitates to express views on this matter, as insufficient experience is to hand to make any sound comparison, it does not seem fair to make comparisons between air-cooled engines operating on normal fuel and compression ratio and a special water-cooled motor using a compression ratio in excess of 6 to 1 and doped fuel, and further leaving the weight of water and radiator out of account (where 1.45 lbs. per hp. is quoted).

(6) Colonel Vincent's statement to the effect that "the radial form of engine was adopted on account of cooling difficulties" is in the nature of a personal opinion not borne out by investigation.

One twelve-cylinder air-cooled Vee type, giving 220 hp., produced by the British in 1917 and subjected to severe experimental test in the dynamometer and in the air, cooled as satisfactorily as any radial yet seen by the writer and incidentally a good deal better than most water-cooled engines of similar power.

The main disadvantage of the air-cooled Vee engine lies in the necessarily greater length compared to the water-cooled unit, due to the space required between cylinders on an air-cooled engine.

Experience in Europe has shown that the large Vee engine with 40 hp. cylinders has by no means unsurmountable cooling difficulties.

The writer's view of the general situation of the air-cooled aircraft motor is as follows:

Little work comparatively has yet been done on the nine-cylinder single row 300-400 hp. air-cooled radial engine; as no really satisfactory motor of such type has yet been produced, the mechanical difficulties of such a motor are by no means easy of solution and will need much careful work before the standard of maintenance and reliability set by the best water-cooled line or Vee engines is equaled.

An engine of such power will have an approximate minimum overall diameter of 48 in., and the question of cowl-ing and fairing for minimum resistance with good cooling will call for a deal of careful design and investigation.

When experience is obtained by airplane and power plant designers and test staffs, a considerable improvement on present fairing methods will no doubt be rapidly obtained. The problem can hardly be said to have begun to exist, as large air-cooled radial engines have not been used other than experimentally and in small numbers.

By enclosing and streamlining as far as possible the valve gear and springs it is probable that a considerable reduction in head resistance can be obtained; up to the present this feature has had little or no attention.

In the light of present day knowledge it would seem that if the air-cooled motor for military work is to compete with the water-cooled engine in the 400-hp. class, the only hope lies in the high efficiency cylinder developing a mean effective pressure in excess of 130 lbs. per sq. in. and using high compression. Experience has shown that up to the present high mean effective pressure is necessary owing to the fact that the successful air-cooled cylinder has proven to be fairly heavy on a basis of weight per cu. in. volume swept. To design a cylinder of 150 cu. in. swept volume to weigh .65 lbs. per b.hp. requires considerable finesse.

The use of high compression has been shown to improve air-cooled performance, not only as regards power and fuel consumption, but cooling efficiency as well, and in this connection the use of fuel dopes allowing of compression ratios in excess of 6 to 1 gives promise of further improvement.

On single cylinder test engines, brake mean effective pressures of 135 lbs. per sq. in. have been regularly main-

tained, this with blast velocities lower than obtained under almost any flying condition in a pursuit machine. Such performance has up to the present only been produced under favorable conditions that would not exist on a multi-cylinder engine under service conditions, but this is likely to be balanced by the improved fuels for high compression and eradication of faults which were shown up on the cylinders while giving the above mentioned performance.

High performance from air-cooled cylinders is not obtained by the first casual idea produced on the drawing board, nor during the first run on the test block, but is the product of long and exacting test and design work.

Owing to the wide variation in climatic conditions existing between the Mexican Border and Alaska it would appear that the air-cooled has many advantages for military use in this country. It would be unfortunate if the possibilities of the air-cooled be left untried owing to an attitude of mind that condemns without investigation, and because all the problems have not already been solved. What would be the present state of aviation had the pioneers thought on such lines?

S. D. HERON,

Power Plant Section, McCook Field.

## Air Operated Brakes

Editor, AUTOMOTIVE INDUSTRIES:

Permit me to congratulate you on the engineering issue of AUTOMOTIVE INDUSTRIES. I was especially interested in the article written by Bradley and Gerster, on "Four-Wheel Brakes."

To my mind, there is no question that the front-wheel brake is bound to come, although it may be confined to the better class car. The most serious objection to the front-wheel brake design is the large number of parts and universal joints which are necessary to insure correct operation at all wheel angles and spring deflections. Another handicap is the necessity of perfectly equalizing all four brakes. I may add that I believe in applying all four brakes simultaneously.

But these difficulties all disappear if a leaf is taken from the history of railroad engineering: by using compressed air as operative force on the brake shoes. Such a design eliminates all levers, joints, rods, brake equalizers, etc.; in fact, all parts which clutter up a chassis and are apt to produce rattles.

Most automobiles are equipped with a power tire pump, which would only have to be redesigned for permanent operation, and an air tank would have to be added for storage purposes. A few simple pipe lines and flexible metal hose connections would complete the layout. The brakes would be operated by opening a valve from the air pressure tank by means of a pedal or hand lever on the steering post. I have been working on such a design for the past three years, in my spare time, and have finally arrived at a practical solution of the problem. My standpoint on this question seems to be confirmed by the brake design of the Hispano-Suiza, where the car itself supplies the power for applying the brake shoes.

It seems to me that a discussion by the engineering fraternity on air-operated brake design would be of benefit to the automobile industry.

E. H. DELLING, Chief Engineer,  
STANLEY MOTOR CARRIAGE CO.

A MEETING of the Executive Committee of the American Engineering Standards Committee was held at Washington some time ago to discuss the possibility of securing government support for the valuable work which this committee has in hand. Representatives of engineering societies and Government Departments attended.

# Knowledge Is the Beginning of Understanding

It is necessary for the manufacturer to have knowledge of the workers' viewpoint if understanding is to be reached. He should welcome good suggestions regardless of their source. Mr. Tipper discusses a speech recently made by a labor leader and recommends it for examination.

By Harry Tipper

**I**N the Editorial Section of the New York *World*, Sunday, June 19, there was a speech by John H. Donlin of the American Federation of Labor, which contained many interesting statements. A good many of these statements would agree almost in their entirety with remarks made by many of the industrial leaders.

On the question of production, for example, Mr. Donlin very definitely agrees with the necessity for more production and for greater efficiency in production:

"Wealth cannot be distributed until it is produced, and the more we produce, and the more efficiently we produce, the richer we will be, the more our dollar will buy; the less we produce, the dearer it will be and the less we can buy."

On the question of production and the necessity for foreign commerce, Mr. Donlin's statement is equally interesting:

"Labor, capital and management must co-operate, must recognize mutual responsibility. To keep everybody working, upon which hinges the well-being of the masses, we must keep our factories running at full blast. We must export merchandise which can only be sold in foreign markets in competition with native products. The thing that recommends the purchase of our goods is the price, and if the American standard of wages will prevail, a standard of efficiency must prevail in accordance."

Perhaps the most interesting statement which he makes, because of its unusual source, is the statement regarding strikes—jurisdictional strikes, which are very frequent in the building trade and which are hampering that industry very seriously:

"My experience in this movement at least has taught me one thing—that jurisdictional strikes generally are the result of demagogues and aspirants for office, or they emanate from a class of workers which it is impossible to satisfy, or for reasons that will not stand for the magnifying glass. When it is all summed up, we can attribute it all to selfishness and absence of justice, equity and fairness. Only those organizations will endure which correct abuses, make reforms, eliminate contentions, create amity, mutualism, a feeling of mutual dependence among men."

This speech, printed by the *World*, reached a great many people, but it is questionable whether it was read by anyone not in sympathy with the labor union movement, outside of a few students who are willing to read material on the subject from any source.

Unfortunately, it is still true that we approach the human question in industry pretty much in the same way

that we approach the question of our political party. Very few Republicans I know read Democratic newspapers and documents, and only a small number of my Democratic friends have anything to do with Republican information. It is quite unusual to find a man in industry, with the responsibility of management, who will read the prepared definitions of the labor leader or who will approach his reading of them with a desire for information.

Several years ago, when I first started active work in the analysis of the human difficulties in industry, I made a number of addresses before groups of manufacturers. Very frequently many of them were there simply to find out the weak spots in my argument and to tear down, if possible, the structure I was building up. They were not in sympathy with the discussion of the matter, and they did not want to have any new ideas interjected into their beliefs.

We have come a considerable distance since that time and there are many matters openly and generally discussed that were avoided in those days, although that is only a few years ago. We are not yet at the point, however, where manufacturers on the one hand and the labor leaders on the other are willing to read what may be written or said upon this subject without regard to its source and its probable affiliations.

This tends to slow up the whole movement toward a better understanding of the factors involved in the difficulty; it perpetuates the errors and the prejudices; it lends strength to traditions which have nothing more than custom to justify them.

Here is an important leader of labor in a trade which has been heavily involved in strikes and interruptions, where graft has been rampant between the labor leader, the supply man and the contractor, and where the extortion has been generally suspected, if not openly admitted. The terms in which this leader speaks indicate that he is endeavoring to draw the building trade unions into a more sensible, normal and just method of dealing with the problems. Unless his words are utterly at variance with his actions, he believes the present situation is due just as much to the iniquities of labor as it is to the iniquities of the employer.

Under such circumstances the statements of this leader should be welcomed by the leaders of the manufacturers' organizations in the field, the agreement in their viewpoint should be publicly admitted, the extent of their agreement should be publicly emphasized, and, on the basis of that public commitment, a program of constructive development should be erected.

This has not happened. No encouragement visible to the observer has been given to the constructive address delivered by Mr. Donlin before the American Federation in its convention. On the other hand, this address has undoubtedly stirred up the radicals within his own organization, and they will find in it plenty of text to prove that Donlin is deserting the cause of labor to some extent and compromising with capital.

Some manufacturers have lost an opportunity at this time to start the machinery for the solution of problems that are very severe and that have worked to the detriment of the whole building trades movement.

No man who is charged with the responsibility of an investment of millions of dollars and the government of thousands of workmen is fulfilling that responsibility if he neglects to keep himself informed on the best ideas in labor and the tendency of the most constructive thoughts in labor circles.

Because the American Federation of Labor represents the largest body of organized development in skilled labor circles it is to be expected that some of the leaders in that movement are thinking constructively of its future and its future necessities.

I may not believe in labor unions *per se*, but the character of my belief in that matter does not affect the

necessity for my understanding of the labor union, its tendencies and the development of its best thought.

Constructive and logical suggestions do not appeal to the majority at any time. The labor leader who offers constructive and advanced ideas is not likely to be followed by the rank and file of his union. He must fight for these constructive ideas within his own organization and fight a discouraging battle for every future move. The same thing is true in manufacturers' organizations.

When the men of most constructive character and thought in the management of industry and the organization of labor approach each other so closely in their understanding of the necessities, the agreement should be emphasized. The foundation of common understanding should be seized upon to provide a basis on which the constructive development can be erected.

In the last paragraph of Mr. Donlin's speech, which is the third paragraph quoted in this article, he is very illuminating, and few executives in the management of industry but will agree with his description of the trouble and the solution.

I recommend this document as interesting material for the man who has at heart the solution of the present human difficulties interrupting the progress of industry.

## Thirty Years' Constant Service from One Car!

**T**HIRTY years' constant service is the record of the twin-cylinder Panhard-Levassor car with which Abbe Gavois, a village priest at Rainneville, near Amiens, entered Paris recently amid the plaudits of an enthusiastic crowd.

In December, 1891, this high-wheeled, tiller-steering, 3-hp. automobile came out of the Panhard-Levassor factory, bearing serial number 8. It was purchased by the mayor of Troyes, who, after a couple of years' service, sold it to Abbe Gavois, its present owner. For nearly twenty-eight years the ancient Panhard has been used by the priest for visiting distant parts of his parish, and during that time it is estimated that it has covered 100,000 miles without ever going more than 100 miles from home, and without ever having attained a speed of 15 miles an hour.

During the war the old car remained on the battle-front and was used by the priest for his journeys among the troops and to visit the few parishioners who had refused to move to the rear. The German troops took possession of the village in 1914, but were not interested in the relic or its owner. When they fell back from their rush on Paris the car was put on the road again by special permission of the general commanding the British troops holding this section of the front.

The end of the war found the old Panhard and its sturdy owner in excellent condition, in strong contrast to the devastated country around them. After having refused several pre-war offers to sell "the ancestor of the automobile industry," Abbe Gavois resolved, a few weeks ago, that he would part with his almost lifelong friend and give the proceeds to a fund for the relief of the war-stricken inhabitants of his parish.

The offer of the Panhard-Levassor Company to bring the old car to Paris on an automobile truck was indignantly refused by the priest. After lighting the hot tubes, the ecclesiastical motorist climbed up behind the steering tiller and at 4 a. m. set out on the last journey to Paris, 95 miles away. He slept just outside the city that night, and the following morning made a triumphal

entry through the gates of the capital, paused for an instant in front of the monument erected to the memory of Emile Levassor, the builder of the car, then rolled down the Avenue de la Grande Armee and the aristocratic Champs-Élysées to the showrooms of the Panhard-Levassor Company, where the car was placed on exhibition prior to being offered for sale by auction.

The veteran has two cylinders of 70 by 110 mm. bore and stroke, automatic inlet valves, hot tube ignition and wick carbureter. Its timing gears and its change speed gears are exposed, its clutch is of the now obsolete brush type, and final drive to the steel-shod wheels is by a single chain, the tension of which is regulated by moving the axle and springs. In 1912 the car was completely overhauled by the Panhard-Levassor Company, without being modernized in any way.

Panhard-Levassor car reported to have seen 30 years' continuous service. Is thought to have traveled 100,000 miles without exceeding speed of 15 m.p.h. Has two-cylinder, 3-hp. engine with hot tube ignition and wick type carburetor

## Commercial Bribery

A BILL is on the national legislative calendar which is interesting to all commercial enterprises, but concerning which little has been said. It is known as House Bill 5632. It provides punishment for any employee, partner or officer of a firm who shall accept bribes or gratuities unbeknown to his employer or business associates.

This bill has been promoted by the Unfair Competition Bureau of the Paint and Varnish Industries. The facts on which the need of this bill are based have been known to many industries for a long time, but were written into records by the Federal Trade Commission. It has been shown in hearings that it was a frequent occurrence for varnish and paint firms to pay certain employees of customer firms a definite amount per gallon of material purchased. The better firms have objected to this practice, and at present practically all firms in this industry have signed the fair dealing code. It is also told that certain oil companies have maintained card indexes of employees of customer firms and the price they demanded for

recommending the various oils sold by this firm.

The automotive industry is a heavy purchaser of varnish and oils and this industry may well be interested in this pending legislation.

## Lubrication of Chassis Parts

THERE are evidences that more attention is being given to ways and means for providing better lubrication of chassis parts, or what is more to the point, decreasing to an absolute minimum the number of parts which require hand lubrication. Experiments are being made, for example, with flexible members for use in place of spring shackles, and many manufacturers are investigating various types of oil-less bushings which appear promising.

There seems to be a quite general agreement that the grease cup will in time disappear from the passenger car chassis. It is at best a messy job to fill a grease cup, and too often the grease is not forced to the surface it is intended to lubricate. As a result, rapid wear with consequent rattle takes place and the parts affected require early renewal. Those systems which force grease under considerable pressure to points where it is required are a considerable improvement over the ordinary grease cup, but even with this system lubrication is often neglected, and grease is at best a poor lubricating medium. It is sometimes referred to as a sponge for carrying the oil which gives it the only lubricating value which it possesses, and the oil is not always released until heat generated by friction causes the grease to flow, and wear may then have taken place.

Several car manufacturers and one or two parts makers have designed systems for feeding oil to all points of the chassis requiring lubrication, but the cost and complication of these systems is a serious drawback to their general adoption. Devices arranged to feed oil by wick or as a result of vibration are promising, at least for certain applications, so long as they are made readily accessible for filling, cleaning and adjustment.

The whole subject of chassis lubrication is one deserving of further study. It has an extremely important bearing upon the convenience and cost of upkeep, as well as upon service, and there are few more important items than these demanding the attention of car and truck manufacturers to-day.

## Pollyanna for President

THE pessimist has been much condemned lately. His baneful influence on business conditions has been recognized and he has been very properly squelched when he attempted to sing his song of gloom. But there is a type of professional optimist whose influence is just as evil.

This is the sort of optimist who closes his eyes to facts and implies that all must be well simply because he says so. He is the type of salesman who sits around the salesroom with a cheery smile, saying business is good, despite the fact that he hasn't made a sale for a week.

A sincere regard for facts does not necessarily im-

ply pessimism. Sane optimism finds its very foundation in facts, however doleful the facts themselves may appear. Optimism is no relation to foolhardiness. A recent advertisement in *Printers' Ink* expressed the truth briefly and forcefully. We forget what the advertisement was advertising, but that doesn't matter. Under the heading, "Grin, But Don't Bear It," this advertisement said:

"Would you like to hold stock in a company with Pollyanna as president?"

"The disposition to grin is useful, perhaps, but one must know how to handle it, especially in business. A knowledge of all the facts is really more useful."

A careful search for facts and an intelligent interpretation of those facts may be more difficult than merely grinning, but it will be more productive of results as well.

## A Transportation Project

THERE are movements of a local nature which have a greater significance than appears on the surface. Such is the present movement on behalf of a bridge across the Hudson River, which will connect Manhattan by a direct open-air route with New Jersey. Previously all transportation for motor cars across the Hudson, south of Poughkeepsie, has been subjected to the inconvenience of more or less efficient ferries. Recently the building of a tunnel from Manhattan to New Jersey was started and doubtless will proceed. But, in the words of a veteran and enthusiastic motorist, "Who wants to ride in a dark and smelly tunnel?"

The Hudson River bridge project was started in 1873 or thereabouts under the direction of Gustav Lindenthal, who has a position all his own in bridge building. Mr. Lindenthal has been connected with the movement from that time on. The first plan was for a railroad bridge, and once its building was authorized. Necessary economies, perhaps a lack of vision on the part of some men in his places, and other reasons have kept the project back.

Only recently the project has been revived, and the space allotted to vehicular traffic has been greatly enlarged. Practically every bridge engineer in the world has expressed his views, and, under the direction of Mr. Lindenthal, these views have been coordinated for safety and utility. The array of engineering names behind this project does not leave much doubt as to the thoroughness of the preparation.

It is said of this bridge that it will carry traffic equal to twenty tunnels, and, despite the high figure given for its cost, will cost only half of the total for the twenty tunnels.

The project at present is proposed as one for private enterprise. It is suggested that, with the proper introduction to the public, bonds can be sold to build the great structure. The railroads and similar interests are committed to it. As a first step toward the carrying out of the project, the Hudson River Bridge and Terminal Association has been organized. This is practically a promotion plan for the bridge project. Many men and business organizations have joined this

Association, paying a fee of \$100. This Association will organize the bridge building project.

It is suggested to the automotive industry that an enterprise of this sort means much to the industry. It would greatly add to the value of a vehicle owned in the lower Hudson River community. It would be a precedent for similar work in Philadelphia and other river-bound cities. The sale of only one car would repay the factory or the dealer for his outlay in this connection. Those interested can obtain further information from the Association at 7 Dey Street, New York City.

## Stabilizing Business

"HOW is business?" was asked of a parts maker the other day. "Jumpy," came the reply. "We can't make any plans; can't actually get into production or begin to build up our organization. Orders come in one day and are cancelled a week later. We have one good week, then a bad one." The quotation is typical of business at the present time. It is interesting to attempt to analyze the reason for such a condition, not only because it is specially acute just now, but because it is always more or less true of our modern industrial organization.

If the manufacturer knew for certain how many people were going to buy one of his cars during the next twelve months, it would be a comparatively simple task to order material and route production accordingly. But it is impossible to ascertain such facts accurately. Obviously, however, the more nearly accurate sales estimates are made, the more steady and economical will be the factory production. And while it is not possible to determine a sales figure to the last digit, it is perfectly possible to make a closer estimate than is commonly done.

The factors of merchandising have never been analyzed and examined as carefully as have those of engineering and production. Mechanical knowledge has progressed at a rapid rate during the last twenty-five years, but merchandising methods have failed to keep pace with that advance. Sales analysis proceeds upon scientific lines only in a few cases.

More attention in the future must be paid to determining sales possibilities, to territorial analysis, to discovering the factors involved in selling, and the relative value of those factors to one another. The psychological aspect of the merchandising problem must be studied and intensive work must be done in merchandising and commercial research. A few manufacturers are going forward along this line; others will follow.

The lack of knowledge of markets and of selling possibilities has a far-reaching effect in modern industry. So closely related are the various units that the failure in one department of one company may vitally affect thousands of persons and scores of other companies. Both enlightened self-interest and the recognition of a moral obligation in industry call for strenuous efforts along scientific merchandising lines.

Send in your name for a copy of Index of Vol. XLIV of AUTOMOTIVE INDUSTRIES.

## Parts Factories Short of Orders

Makers Expect Dull Two Months  
But Are Optimistic About  
Future

NEW YORK, JULY 5.—Makers of the most important component parts which go into the manufacture of automobiles are conservatively optimistic about the future. They have no illusions regarding the next two months, and they state frankly that they have few specifications on their books for July, with virtually none for August. In view of this situation and the probable slump in retail sales for the next eight weeks, it is highly probable a considerable number of parts plants will be virtually closed for a month or more while awaiting fall orders.

The optimism is based on the firm belief that the worst of the period of readjustment is over and that after the next sixty days, conditions will gradually improve. As the representative of one big company phrased it: "I don't look for much business before January, but business may surprise us and we may have much more than we expect long before that."

A good many parts factories got more business the latter half of June than they expected and they frankly admit that the same happy condition may prevail the rest of the year. They are convinced that fundamentally the outlook is better than it has been for eighteen months. This is true not only in the United States but in Europe as well.

As a matter of fact the European situation is one of the most encouraging features. Germany seems to have settled down to a grim determination to meet the reparations terms. The British coal strike has been settled and a strike in the British engineering trades has been averted. The Silesian tangle is being straightened out and there is a stronger prospect than there has been for years for a satisfactory solution of the Irish problem. The new tariff which Congress will adopt promises to be the biggest stumbling block in the way of foreign trade.

### Falling Prices Checked

In the domestic field there also are numerous encouraging factors. The chief of these is found in the fact that the precipitate fall of commodities seems to have been checked and while many readjustments remain to be made, prices have been stabilized to a certain extent. The new tariff probably will bring a gradual upward trend in some fields and these advances probably will be reflected in retail prices, especially of food products, which still have a long drop to make before they will adequately reflect the decline in wholesale prices.

The crop prospects generally are gratifying and the fact that in several European countries the harvests will be

## NEW RECORD FOR FORD WITH 4360 CARS A DAY

DETROIT, July 5.—The Ford Motor Co. set a new high record for monthly production with an output of 108,962 cars and trucks in June in the Detroit factory and 22 assembly plants throughout the country. Production has been increasing steadily since early spring and shows substantial gains over the same period last year.

The second quarter of this year shows an output of 301,796 against 220,878 for the same period last year, a net increase of 80,918.

Despite the fact that the plants have been running at maximum capacity, the demand for products is not being met, officials say, and there are many thousand unfilled orders ahead so that Ford sales are still limited by manufacturing facilities rather than marketing possibilities. This is true particularly with respect to closed cars, for which the demand is unusually heavy.

The estimated output of the Ford company for July is 109,000 cars and trucks, or a production approximating 4360 daily for 25 days. Since the assembling of cars is handled during an eight hour work day only, the hourly output will be approximately 545 cars. In other words, one Ford car or truck will leave the assembly line every six and a half seconds.

shorter than had been expected, will increase export demand. The new tariff was framed specifically to aid the farmers. These two factors should tend to break down the sales resistance in the agricultural sections and enable the farmers to liquidate some of their bank loans. Conditions also are improving gradually in the south and business certainly is no worse than it has been reported, especially in automobiles.

In the industrial sections unemployment probably will increase somewhat during July and August, but this is the normal mid-summer condition and there is every reason to believe that it will be preliminary to a slow but steady march forward after the middle of September.

### June Sales Amazing

An amazing sales record was made in the retail automobile field for June and in most districts the volume of business ran ahead of May and even of April. There are no indications yet of a July slump but sales are not likely to continue at the pace set last month.

Parts makers are the first to feel a slump and the first to recover from it. For that reason there is reason to believe that within sixty days their plants will be running on a better basis than they dare hope for now. Their June business ranged from 25 per cent. to 50 per cent. of that done in May.

## Two Measures Cover Truck Dumping Evil

Section of Permanent Tariff Provides Duty—Graham Resolution Hits Speculators

WASHINGTON, July 1.—Two measures to prevent reimportation of American made trucks are now pending before Congress. Chairman Fordney of the House Ways and Means Committee says Section 317 of the permanent tariff bill fully covers this important issue. Congressman Graham of Illinois has a joint resolution before the Ways and Means Committee which would practically prohibit reimportations and favorable action on the resolution is promised by Chairman Fordney as a means to expedite this legislation.

Section 317 of the tariff bill reads as follows:

"That upon the reimportation of articles once exported, of the growth, product or manufacture of the United States upon which no internal tax has been assessed or paid, or upon which such tax has been paid and refunded by allowance or draw back, there shall be levied, collected and paid a duty equal to the tax imposed by the Internal Revenue laws upon such articles, except articles manufactured in bonded warehouses and exported pursuant to law, which shall be subject to the same rate of duty as if originally imported, but proof of the identity of such articles shall be made under general regulations to be prescribed by the Secretary of Treasury."

If this item is included in the permanent tariff when finally enacted it will put an end to underselling the American market by speculators who have purchased army trucks abroad at ridiculously low prices.

Because of delay incident to the debate on the tariff bill the Graham resolution may be rushed through the House and Senate. It provides for an assessment of 300 per cent on reimportation of war supplies, based on American valuations. This rate is sufficient to equalize prices in this country and halt the flood of remanufactured or altered trucks sold by the army agents which found their way into the hands of speculators.

### NEW DILUTION GAGE

CHICAGO, July 2.—An instrument for determining the dilution of crankcase oil has been placed on the market by the Lubricating Appliance Mfg. Co. under the name of the Larcliff Dilutometer. It is in the form of a hydrometer on the stem of which there is a sliding tube with scale marks lettered "Danger," "Poor," "Fair" and "Good." The sleeve is set so that new oil will show "Good," and the scale mark to which the instrument submerges then indicates the degree of dilution. Tables for different oils have been worked out for the use of the operator.

## Reserve Board Finds New Prices Paying

### Fair Profit Shown by Leading Companies but Smaller Makers Suffer

WASHINGTON, July 5—Bankers throughout the country are watching the effect of the recent price reductions in the automobile trade with interest. The survey of general business and financial conditions for June as completed to-day by the Federal Reserve Board shows that the month has been relatively quiet and of temporary reaction marking the close of spring demands while arrangements for autumn trade have not been completed. Prices in all lines tend more toward stability and the downward movement during May was the smallest since the decline first began. One of the encouraging signs is the recovery of agriculture, though there is some hesitation in buying.

Discussing the automobile situation, the Federal Reserve Board says:

"May shipments of automobiles by factories producing three-fourths of the total output of the country show a falling off from the April figures. May shipments amounted to 18,608 carloads, as compared with 20,087 carloads during April, although driveaways increased from 14,197 machines in April to 15,200 machines in May. Thus far this year carload shipments have been greater than last year only during April, but driveaways have been much less in every case and during May were only slightly over 20 per cent of the May, 1920, figure.

"Manufacturers of popular standard makes who build their own cars are able to make a fair profit and do a good business at present prices, but assemblers, as well as some of the smaller and weaker companies find their overhead increasing as competition to supply the restricted demand becomes keener."

### Dyneto Renames Officers; Finances Show Gains

SYRACUSE, July 5.—Charles L. Amos has been re-elected president and chairman of the board of the Dyneto Electric Corp. Others returned to office are Vice President H. B. Leary; Secretary John C. Boland, and Treasurer Jacob B. Stemmler. Directors re-elected are Charles L. Amos, Jacob Amos, John C. Boland, Jacob D. Stemmler, George H. Dennison, James G. Grant, all of Syracuse; R. M. Owen and H. B. Leary of New York and H. M. Ballard of Chicago.

The committee of creditors created Nov. 20 by order of Judge Ray in United States court will continue, the stockholders' action not affecting the work of the five men named to conserve assets of the corporation. The company is slowly throwing off the financial difficulties which forced creditors last

fall to begin a friendly suit in equity, according to the statement made by one of the committee.

The five men named on the committee are members of the board of directors. They are Percy H. Ridings, E. A. Hardman and C. Hamilton Sanford of Syracuse, and H. W. Barnard of Rome and William E. Lowther of New York.

When the court order was made last fall, liquid assets of the corporation were \$1,552,550.36 and liabilities \$690,037.39 with the business ordered aggregating more than \$8,000,000. The financial difficulties were attributed to the slump in automobile manufacturing and failure of sales to materialize.

## Federal Conflict Follows U. S. Tax on Manufacturers

RALEIGH, N. C., July 5.—While attorneys are advising one or another of the 92 automobile manufacturers liable for the \$500 tax recently invalidated by the United States Supreme Court not to pay this tribute, State Treasurer Lacy is sending out letters calling for the payment of this state tax, and there is another North Carolina federal conflict.

Treasurer Lacy is proceeding under the advice of Attorney General Manning, who reads the highest court's opinion as no bar to the recovery of the tax imposed upon these outside dealers. Judge Manning thinks that the Supreme Court merely invalidated the discriminatory section and makes all dealers equal.

The last session of the general assembly put in a proviso making the act applicable to all alike, if there was any trouble about it, and Attorney General Manning, after quoting that section, says:

"The effect of this provision, in the light of the decision of the Supreme Court of the United States is to strike out from section 72 of the revenue act of 1921 the proviso which, under this opinion, discriminates against non-resident manufacturers, and to leave the remainder of the section intact. Thus, in the opinion of this office, you should continue to collect the license tax of \$500 from those engaged in the business of selling automobiles and automobile trucks in the state, and you must likewise collect it to the full amount from those resident manufacturers who have heretofore paid only \$100."

### TULSA AUTOMOBILE SOLD

TULSA, OKLA., July 2.—The plant of the Tulsa Automobile Mfg. Co. has been sold to D. M. Witt of Oklahoma City by R. M. McFarlin and his associates. Floyd Thompson, former sales manager of the company, will be interested with Witt and will be manager of the Witt-Thompson Motor Co., which will be the new name of the concern. The company has dealers in California, Oregon, Washington, Missouri, Colorado, Arkansas and Oklahoma, and an export department in New York. The new company takes over all the assets of the old but none of its liabilities.

## Sales Continue High As Summer Sets In

### June Business in New York Equals Expectations—Look for Good Season

NEW YORK, July 1—June has closed with both retail and wholesale sales of passenger cars in the New York territory running strong. Several medium priced cars have run far ahead of their April and May records and a large number of cars which were not selling at all in April and May, because they had not yet reduced prices, have had brisk sales, with the result that the total of June sales and deliveries will be the largest for the year.

Despite persistent rain sales have not shown any decided falling off as the month has drawn to a close and there has been no indication of any July and August slackness beyond that which is normal when large numbers of automobile owning people are away on their vacations.

Buick has closed its June books with the second largest month in the history of the New York branch. The record month was in 1918 but it exceeded the business of the past 30 days by only a few cars. Franklin's June was better than 1920. Oldsmobile exceeded its May record and almost equalled the heavy sales of April, business in the territory outside New York City being especially good. Maxwell's sales curve has climbed steadily through April, May and June.

There are a few cars which have not sold well and several of the high priced makes have had some slowing up, as compared with their April and early May records.

In general dealers are agreed that business is good.

Used car demand is brisk but buying is extremely close.

### STARK-INLAND ASKS MORE TIME

ST. LOUIS, July 5—Creditors of the Stark-Inland Machine Co. have been asked to grant an extension of six months on their accounts. The business of the company is said to show a substantial profit and the promise is made that any sum above the actual running expenses will be used in the cutting down of obligations. Creditors whose claims are less than \$100 will be paid in cash. The bank which is the largest creditor is said to have agreed to give such financial assistance as may be necessary for the proper conduct of the business if the other creditors will grant an extension of time.

### ROSE GUARANTEES PRICES

HASTINGS, NEB., July 5—The Frank Rose Mfg. Co., manufacturer of Rose specialties, has guaranteed its prices up to Jan. 1. Dealers have been informed that if manufacturing costs can be lowered all stock purchased after July 1 will be protected up to Jan. 1.

## Army Truck Disposal Opens Way to Sales

**Future Markets Being Created  
As Vehicles Exemplify Value,  
Declare Officials**

WASHINGTON, July 1—Distribution of surplus trucks, passenger cars and tractors from the army to the various highway departments has stimulated sales and developed service rather than retarded the trade, according to the opinion expressed to-day by officials of the Bureau of Public Roads. Emphatic denial was made that the Government had distributed unserviceable motorized equipment to the States, and it was pointed out that all unserviceable vehicles were sold under the auspices of the Motor Transport Corp.

The Federal agency stated that no highway equipment was dispatched to the State highway officials except upon requisition and after a complete inspection and report had been submitted. The Bureau of Public Roads will have approximately 4000 army trucks of varying sizes and 1800 passenger cars to dispose of under the terms of the Army Appropriation Act, which went to the President for his signature last week.

It is the contention of Government officials that the automobile industry, as a whole, particularly the motor truck division, has materially benefited from the distribution of surplus war material. It is stated that handing out approximately \$80,000,000 worth of samples must eventually bring returns to the manufacturers and dealers. As an illustration, it is declared that one American truck manufacturer had restored confidence in his product by the development of service in the various states where the equipment had been placed with the highway commissions.

This motor vehicle had been condemned as inefficient for several months prior to the armistice, but it soon proved its worth when put to domestic uses. In fact, one state which had accepted the consignment of trucks, reluctantly, finally adopted it for standardization purposes, and has expressed a preference for the models manufactured by this particular firm. It is further declared that these trucks actually in use and giving as satisfactory service as could be reasonably expected because of their present physical condition, make it easy for a truck salesman to sell newer and improved models to the state.

### 87 Per Cent Now Delivered

The statement of allotments and deliveries of trucks, Fords and other automobiles from surplus war materials to the several states and retained by the Department of Agriculture to June 1, 1921, shows that the deliveries amounted to 27,983 vehicles, of which 21,115 were trucks delivered; 2770 Fords delivered and 433 other automobiles, making a total of 24,318 vehicles, or 87 per cent, delivered.

## WHIP FACTORY QUILTS AS DEMAND SLACKENS

WESTFIELD, MASS., July 2—The coming of the automobile has made such serious inroads on the whip industry that the United States Whip Co., the largest factory of its kind in the world, has suspended operations. The company has been operating on a four-day basis.

## Ohio to Seek Repeal of Truck Weight Limit

CLEVELAND, July 1—State Senator J. F. Burke of Elyria, gave his pledge to the Cleveland Automotive Trade Association at a meeting in the Hotel Winton that he would lead a fight at the next session of the Ohio General Assembly to restore to Ohio highways the 14-ton maximum of truck and load combined.

A measure passed this year limits the weight to 10 tons. The Cleveland organization joined with the State and other kindred bodies to fight the measure, and delegations asked the Governor not to sign the bill. The executive approved it, however.

Senator George H. Bender of this city, also promised to give his aid to the movement, as did E. J. Shover, secretary of the State association.

The action in this city is the opening gun of a battle that will be waged against the bill by all automobile trade associations in the State under the leadership of the State body. Senator Burke, Shover and other speakers declared that the measure was discriminatory; that it would cause thousands of dollars worth of trucks to be put out of commission, and that it was a serious handicap to the motor transportation facilities of the commonwealth.

## Construction Costs on Highways Decrease

CHICAGO, July 1—State contracts for 29 miles of concrete roads on the Chicago-St. Louis route have just been let at a marked reduction from the first bids received and refused because they were excessively high. The awards show a drop in the price of cement compared with the bids of last February of 14.4 cents a barrel, or of \$476 a mile.

Governor Small, it is said, still considers the bids too high but expresses satisfaction that the figures are well within the \$30,000 limit set by his office.

## FRUIT GROWERS USE TRUCKS

INDIANAPOLIS, July 1—William Guinot, distributor in Southern California for the Swinehart Tire Co., was in Indianapolis this week. He says the fruit growers of his territory are solving their own freight rate question by using trucks and he says the major portion of his tire business is developing into a truck tire business.

## Truck Outlook Fails to Justify Gloom

**Fenn Says Fall Should Bring Considerable Buying—Normal Trade in Spring**

KALAMAZOO, MICH., July 1—That an unjustifiable feeling of pessimism pervades the motor truck industry is the opinion advanced by F. W. Fenn, secretary of the motor truck committee of the National Automobile Chamber of Commerce.

Fenn was the guest of H. G. Stiles, sales manager of the Kalamazoo Motors Corp., during a short stay in the city. He is making an extended tour of the Middle West and visiting motor truck manufacturers in all localities. Going over the situation and the outlook for the future, Fenn said:

"From information we have been able to secure, there is an unjustifiable feeling of pessimism pervading the truck industry. I look for considerable buying next fall, with a slight slump during the winter months, then normal business from next spring forward.

"My reason for holding that opinion is that business in general is coming back and with the resumption of activities in other manufacturing lines, there is bound to be a demand for trucks."

The Kalamazoo Motors Corp. has been able to operate remarkably well, market conditions for the past year considered. The company has been satisfied to maintain its organizations and accept only such business as could be handled at a profit. H. A. Crawford, president of the company, has adopted a conservative policy in the conduct of the business and has made no effort to greatly increase the company's sales force in face of conditions which made that possible only at great expense.

## NEW CHASSIS LUBRICATION

SAN FRANCISCO, July 2—A new chassis lubricating system by which grease is forced to the bearing surfaces of the chassis under high pressure has been developed by the Lathan Auto Supply Co. The Critz lubricator is made of heavy gage brass. The small diameter barrel used makes high pressures easily obtainable, and by means of the ball check head and the special fittings supplied, it is possible to reach all bearings without the use of flexible connections. The lubricator can be operated with one hand by simply turning the handle to build up pressure in the gun, after slipping the head over the nipple. Where a bearing requires a quantity of grease the head is snapped over the nipple and the latch pulled, the head being locked to the nipple, and the amount of grease required is then forced into the bearing by turning the handle. It is claimed that the lubricator is capable of developing 1500-lb. pressure. In installing the system, the old cups are removed.

## Credit Diversion Harming Business

### Loans Increasingly Hard to Get Despite Liquidations—Finance Companies Gain

NEW YORK, July 5 — While the Federal Reserve Board and the big banks are asserting that there is an abundance of liquid funds to meet "legitimate" business needs and that credit conditions are easier than they have been in months, business men in some cities declare they are finding it increasingly difficult to get bank loans adequate to handle the volume of orders they are getting.

It unquestionably is true that enormous sums in frozen loans have been thawed out and that money is more plentiful than it has been in the last 18 months, and quoted interest rates have steadily declined, but reports indicate that there has been no material increase in the volume of funds turned into industrial channels. On the other hand, there is an abundance of call money for Wall Street and for other speculative purposes.

Many banks regard loans of this character as more secure than those made for business and industrial purposes, for the reason that they are amply secured by more or less marketable collateral.

While it is vigorously denied that excessive rates are charged for loans of this nature, there is reason to believe that these denials are somewhat technical. When money was scarcest, banks demanded and received bonuses and commissions in addition to high interest rates. It would be difficult to convince a perfectly solvent manufacturer who had been denied a loan by his bank that the surplus funds of that bank were not being sent to New York or some other financial center to be loaned at a greater profit than would be possible in the home town.

#### Complaints from Up-State

AUTOMOTIVE INDUSTRIES recently received complaints from upstate cities in New York that reputable concerns were experiencing great difficulty in getting bank loans. The subject was taken up with Governor Harding of the Federal Reserve Board. He said that no other complaints of a similar nature had been received and pointed out the low interest rates quoted here. He called the question to the attention of Governor Strong of the New York Federal Reserve Bank, however. Strong stated that it would be impossible to inquire into the complaints without the names of the banks involved and other data which it would be difficult to obtain.

It is somewhat significant that automobile financing companies report that they recently have had more calls for loans than they previously had received for months. This may be accounted for in part by a larger volume of sales, but the finance companies are inclined to believe it represents increasing difficulty in getting bank loans.

Banks have devoted much of their attention for the last year to the liquidation of frozen credits. This process has been successful and they have recovered from industrial enterprises enormous sums which they had invested when the slump came. Bankers in the agricultural sections have been less successful. In some cases business men and manufacturers to whom banks had made loans were carried along until the loans were liquidated in large measure, after which the interest of the banks in these enterprises rapidly dwindled.

It has been contended by the banks ever since the readjustment period began that it would be marked by a survival of the fittest with a gradual weeding out of those weakest financially. There is reason to believe that the "big fellows" will be given stronger banking support than the smaller ones.

## Iowa Investigation Shows Business Better

DES MOINES, July 1 — After four days survey of business conditions in southeastern Iowa, H. J. Lytle and A. J. Knapp, president and secretary, respectively, of the Iowa Motor Trades Bureau, report that the past month has seen a decided improvement in conditions among the motor car dealers of that section of the State. The two bureau officials held dealer meetings in Centerville, Albia, Ottumwa, Fairfield and Burlington, and spend their days in interviewing individual dealers.

Dealers in all of the above towns report that there has been a decided upturn, only a part of which is attributed to price cuts. In the main, however, the improvement has not extended to sales among farmers as the farmer has not as yet returned to the market. During the past month, however, prices of grain have shown an appreciable gain and it is thought that if this continues it will result favorably for farmer sales.

The optimistic dealer reports tally with the personal experiences of Lytle, whose firm, the Burlington-Overland Co., is a large distributor in that section of the State. Up to June 25 the business of the Burlington-Overland Co. has surpassed any June business during the past five years.

#### NORTHWEST CONDITIONS GOOD

SAN FRANCISCO, July 1—The condition of the automotive industry in the Pacific Northwest, throughout Oregon and Washington, is better than has been reported, and is showing continuous signs of improvement, according to W. D. Patterson, head of Patterson Parts, Inc., of this city, who has just returned from a trip through those States. Patterson said:

"Jahns and I found the automobile trade in Washington and Oregon in fairly good shape. It is true that conditions are not all that could be desired, but those concerns selling dependable merchandise are doing a fair volume of business, with a steady, though small, degree of improvement."

## Industry Prospering on New Price Basis

### N. A. C. C. Reports Mid-Year Changes Bringing Increased Sales to All Companies

NEW YORK, July 1—Price readjustment in the automobile industry seems to have been about completed, judging from the final report just issued by the National Automobile Chamber of Commerce, which shows changed prices on the various makes of cars. The new prices in many instances go back to the figures of a few years ago, notwithstanding that the models, in many cases, are bigger, with better finish and such additional equipment as cord tires and improved electrical apparatus.

In the opinion of students of the industry, the mid-year change has now stabilized the industry to a degree that is bringing increased sales to all companies. Carload shipments from the factories during April and May were 67 per cent of the production for the same two months of last year, and there is reason to believe June will be at approximately the same rate.

Compared with the feverish rush of motor cars last spring a two-thirds demand looks to be a big falling off, but compared with normal years it shows that the motor car business is faring much better than other lines.

Good buying power has been shown where prices have been reduced or where it was known that present prices and quality would be maintained. The National Automobile Chamber of Commerce figures show that with more than 8,000,000 passenger cars in use, the replacement demand alone should be about 1,000,000 cars. The production of passenger cars last year was 1,883,000.

While this week may bring a few more changes in cars that have not been reduced this year, it is generally agreed that the mid-year reductions have stabilized conditions in the industry with little possibility of further changes during 1921.

#### Better Cars at Lower Price

The success of the automobile industry has been based on big production and the resulting low prices which insure a broad market. For that reason every effort has been made to produce better cars at lower prices to insure the big productions which make increased values possible. Moreover, in these readjustments of the past few weeks, motor car manufacturers generally have taken into consideration the need for increased car and truck sales by the 35,000 dealers throughout the country.

The truck business continues to be on a par with general business, but with an improved future just as soon as general construction and road building programs get under way and railroads perfect their plans for the use of motor trucks for short haul traffic and in connection with store-door delivery.

## Few Attend Auction of Overseas Trucks

### Conditions in the Transportation Field Blamed for Light Bidding and Sales

NEW YORK, July 5—Lack of interest was the most striking feature of the three-day auction sale here of reconditioned American-made army trucks brought back from England by the Truck Co. of America. There was light bidding because of the small attendance, which did not exceed 50 the last day. Only 90 of the 200 trucks offered were put on sale.

General business conditions in the truck transportation field were blamed for the lack of demand. During normal times there would have been little hesitancy on the part of buyers. One man in attendance stated that while he considered the trucks good purchases, he could not afford to add to his fleet when many of his vehicles were already idle.

Though the vehicles were in good condition and considered bargains, those wishing to buy were reluctant to bid much above \$1,500 for any of the trucks. The sale included 5½-ton Macks, 5-ton Pierce-Arrows, 3½-ton Packards, 3-ton Whites, 4-ton Rikers and 1½-ton Commerce.

Because of the light bidding, the auctioneer was forced many times to reject the bids. The last day \$900 was the highest bid for one of the Packards. While some of the trucks were said to have been sold for around \$2,500, the bidding was carried above the \$1,500 mark by representatives of the company.

In one particular instance, the auctioneer led the prospective buyers to believe that the trucks carried a manufacturer's guarantee. This was not so, the only guarantee being one against defective parts within 30 days of purchase.

It is stated that the Truck Co. of America is planning to auction off reconditioned passenger cars used in Europe during the war. No date has been set for this sale.

## Alena Steam Products to Make Engine Only

INDIANAPOLIS, July 2—Plans for the manufacture of a steam-propelled truck and tractor have been definitely abandoned by the Alena Steam Products Co., which will devote itself entirely to the production of power units. The Hamilton engine, designed by Fred Hamilton, president and chief engineer of the company, is said to have less than 50 moving parts. It is a double cylinder type, with 4½ by 5½ in. cylinders, radial valve gear and piston valves, and develops up to 110 hp. One feature is that the engine takes care of condensation without the use of cylinder drain cocks. Exhaust steam is carried directly from the cylinders to a tubular condenser mounted in the position of

the conventional radiator. Gravity carries the condensed water back to the tank. Pumps supply the boiler.

A feature of the boiler construction is claimed to be that it is impossible to burn the crown sheet. A "mud-ring" at the base of the boiler provides a "self cleaning" feature, and it is said that a clean crown sheet cannot be burned. In addition, the boiler is said to be designed so as to entirely eliminate pitting of flues and to do away with the need for frequent cleaning of flues.

An enlarged type of Bunsen burner, using kerosene, is used. A super-heating device permits of carrying the steam to a temperature of 650 deg. An experimental 5-ton truck has been getting five miles to the gallon of kerosene and 75 miles on 50 gallons of water, according to the officials of the company.

When installed in a truck, the engine crankshaft is connected directly to the differential, and the whole assembly from the rear resembles the conventional rear system of a gasoline truck. The boiler is carried under the hood, which is of the conventional style. The water level in the boiler is controlled and maintained automatically, as is the fire.

The company was organized in February, 1920, and is capitalized at \$1,000,000. It will build two types of power plant, a horizontal one for trucks and a vertical one for tractors. The officers are Fred Hamilton, president and chief engineer; John W. Cadle, secretary and treasurer; George W. Kilman, vice-president; C. E. Gordon, general sales manager; R. B. Hall, plant superintendent.

## Car Registry in Iowa Ahead of 1921 Totals

CEDAR RAPIDS, IOWA, July 2—Linn County automobile registration for the first half of the year has surpassed the 1920 total and dealers estimate that the 1921 figures will be nearly 50 per cent greater than last year. A few days before the half-year ended the total registration was 11,143 cars and trucks as against a total registration in 1920 of 10,054.

This increase is pointed to by dealers as final answer to reports that business is on the decline and that the much heralded revival failed to materialize. Price reductions in the last few weeks brought immediate response from buyers and the easy manner in which automobile paper is being absorbed is taken as indication that the rural midwest sections are far from financially shaken.

### ST. LOUIS REGISTRY GAINS

ST. LOUIS, July 5—Enormous increases in the number of motor vehicles owned by St. Louisans is shown in a survey of the State and city licenses issued by the local offices. Traffic congestion has been so apparent for the past few months that it was certain an increasing number of motor vehicles were using the streets.

J. E. Johnston, supervisor of the St. Louis office, reports that 68,700 State licenses have been issued to date.

## Britain Registers 853,900 Cars to May

### Passenger Cars and Motorcycles Show Largest Gains—Trucks Growth Small

LONDON, June 24 (By Mail)—Failing an exact statement and an official certificate of production corresponding to the yearly returns of the National Automobile Chamber of Commerce the inquirers after British automobile output have to be satisfied with abstract figures collated from various sources and on odd occasions.

Some striking figures are just issued officially by the Ministry of Transport, London, which cover the five months, January to May. They concern the number of automobiles licensed for road use and the sums paid for that privilege by way of the new horsepower tax. The number of automobiles for which licenses were in force on May 31 was approximately 853,900, yielding \$42,180,000 in tax.

The most marked increase is in category "motor hackneys," where the annual licenses have increased from 40,500 to 64,000, while the second quarter licenses were 32,500 as compared with 200 in the first quarter.

The "horse power" class, which includes all private cars, shows an addition of 2000 annual licenses, while the quarterly licenses have increased from 14,000 to 36,000. The increase in the number of licenses for trucks is relatively small, from 13500 to 15000, and it is possible that the numbers shown for this class in the previous return were slightly overestimated.

The number of vehicles for which revenue licenses were issued in the year ended March 31, 1920, was: Private cars, 185,700, as compared with 226,000 in 1921; motorcycles, 278,600, as compared with 370,000 in 1921; motor hackneys, 71,400, as compared with 96,500 in 1921.

The rebate of 25 per cent allowed in the case of "horsepower" vehicles whose engines were constructed before Jan. 1, 1913, has been paid in approximately 31,300 cases, the amount refunded being £133,700. This last item indicates the comparative few pre-war autos now in use.

### OILING SYSTEM CHANGES HANDS

PHILADELPHIA, July 2—The manufacturing and patent rights to the safety oiling system have been purchased from the Charles Kralicek & Co. of Cleveland by the Safety Oiling System, Inc., which has occupied its new building at 2303 Fairmount Avenue, this city. Preparations have been made to manufacture the device on a larger scale than ever before. The Philadelphia company has recently been reorganized and incorporated with W. H. Simon, former general distributor for the safety oiling system, as president. The device is designed especially for use on Ford engines but can be used on other types also.

## Lower Prices Reduce Export Trade Totals

### Trade Index Shows Return to 1913 Volume — Congress Studies Wages Abroad

WASHINGTON, July 2—Speculation has developed of late as to the effect which recent price reduction on automobiles will exercise on foreign trade. There has been unmistakable evidence that the volume of export business in automotive products continues to shrink without signs of abatement. All branches of the Government have manifested unusual concern over trade tendencies, and the legislative branch is giving careful consideration to the possible effects of high tariffs. While there has been a tendency towards improvement in the domestic situation, the foreign prospects are still unsatisfactory, principally because of the unsettled conditions abroad.

The tariff framers, known as the House Committee on Ways and Means, have just received a compilation of wage information showing wages in the automobile industry here and abroad. They intend to use it in designing tariff schedules in Congress and in establishing a protective policy for American workmen and American standards of living. The statistical study of wages in the automobile industry in this country and abroad was based upon wages paid in automobile factories in 1920. While this data was gathered primarily for the lawmakers, it is of far greater importance to American automobile manufacturers contemplating an expansion of their foreign sales.

Secretary of Commerce Hoover has repeatedly warned of the tendency abroad among manufacturers to consolidate for militant export purposes. It is known that our domestic markets could not be easily invaded because of the strength of the American motor car industry. However, the same condition does not apply abroad, where foreign manufacturers, having the advantage of cheap labor and, in many cases, governmental subsidy, may unite to capture foreign automobile markets from American competitors. It is the labor factor that dominates the whole situation.

#### Wage Scale Much Lower

The official information in the possession of the United States Government shows, for instance, that skilled mechanics working an eight-hour day in automobile factories in Lyons, France, in 1920, received an average of 26-30 francs per day, which is equivalent to \$1.80-\$2.10 in American currency. Ordinary mechanics, carpenters, etc., received from \$1.54-\$1.82 per eight-hour day; unskilled laborers working at machines in automobile factories, \$1.40-\$1.68; bricklayers, masons, \$1.40-\$1.68; ordinary unskilled laborers \$1.12-\$1.40; unskilled female laborers at machines,

84c-\$1.40 per day; unskilled female sweepers, etc., 78c-\$1.12.

In Germany, with statistics taken from the German Industrial Inspector's report, in 1914 and 1919 it was shown that the rates per day for car and motor workers in Stettin, was \$1.09 in July 1914; for machinists in December 1919, 44 cents per eight-hour day. These figures, of course, are based upon the exchange which was remarkably low in Germany at the time. Coppersmiths were paid \$1.20 per day in July 1914, and 54c in December 1919; lathe operators, \$1.18 per day in July 1914, as compared to 43c per eight-hour day in December 1919; tinsmiths, \$1.02 in July 1914 and 46c in December 1919; blacksmiths, in July 1914, \$1.09 and 50 cents per eight-hour day in December 1919; cartwrights, \$1.11 in July 1914, as compared with 45c in December 1919; cabinetmakers, \$1.11 in July 1914 and 45c in December 1919; carpenters, \$1.11 in July 1914 and 45c in December 1919; saddlers, \$1.11 in 1914 and 42c in December 1919; painters and varnishers, \$1.07 in July 1914 as compared with 46c in December 1919; drill operators, \$1.09 in July 1914, as compared to 41c in December 1919; planers, \$1.13 in July 1914, as compared with 43c in December 1919, and apprentices 25c in July, 1914, and 11c in December 1919. All of these figures represent the rate per eight-hour day.

In England brass polishing and nickel plating plants pay platers of brass a weekly rate of \$18.25 and the same applied to nickel platers in 1920.

In comparison, the House Ways and Means Committee has statistics from the report of the New York State Industrial Commission, using the average weekly earnings of New York State factory workers in 1914, 1916, 1918 and

(Continued on page 46)

## Gasoline Price Cut Helps British Sales

LONDON, June 24 (By Mail)—The recent reduction of 12 cents a gallon for gasoline has had a stimulating effect on the car trade, though it is reflected chiefly in the light-car class and in Fords. The position of the latter make in Britain has been eventful of late. It has been up against severe competition with the Citroen four-seater from France, especially since the price of the Citroen was reduced by \$500 and is now \$2,000 against the Ford's \$1,200.

The fuel consumption of the Citroen, however, is about half that of the Ford and the taxation is less than half. A while back Citroens were selling in Britain at the rate of 1000 a month and could not be supplied fast enough. The demand for Ford cars thereby was affected seriously but Fords have a more than offset advantage in the van and one tonner. The latter model is selling by the thousand, both this and the van having the market practically to themselves.

The activity in the light-car stock quotations continues, but there is a slump in large car stocks.

## Goodrich Organizes Foreign Sales Body

### International Subsidiary Will Handle Interests in All Countries but Canada

NEW YORK, July 1—B. F. Goodrich Co. has completed the organization of a subsidiary, the International B. F. Goodrich Co., incorporated under the laws of New York, with an authorized capital of \$10,000,000, represented by 100,000 shares of \$100 par value common stock.

The new company will represent B. F. Goodrich Co. in all foreign countries except Canada. It will take over the parent company's interest in factories (with selling organizations) located in France and Japan, as well as its selling subsidiaries in Great Britain, Italy, Spain, South America, Straits Settlements and Porto Rico, acquiring distributors in all foreign countries. It will handle all the products of the parent company, which include tires for automobiles, trucks, motorcycles and bicycles; rubber footwear, and all sorts of mechanical rubber goods and druggists' sundries, in addition to the products turned out from factories in France and Japan.

The great volume of foreign business which has been worked up by the Goodrich company has made necessary an organization like the International B. F. Goodrich Co., through which will be effected centralization of all these foregoing activities, which will be directed from administrative and operating offices located at Akron.

Officers of the new company are B. G. Work, president; W. C. Arthur, vice-president; F. C. VanCleaf, secretary; L. D. Brown, treasurer; H. Hough, controller; F. E. Titus, director of sales, and W. H. Aleen, director of manufactures. The directorate comprises B. G. Work, W. O. Rutherford, H. K. Raymond, L. D. Brown, H. Hough, W. C. Arthur, C. B. Raymond, F. C. VanCleaf, and W. C. Gear.

#### FRENCH REVISE SPEED LAWS

PARIS, June 12 (By Mail)—Abolition of the speed limit is the outstanding feature of the new traffic laws signed by the President of the French Republic last week.

While there is no speed limit for automobiles weighing 3 ton maximum, it has been considered necessary to fix limitations when this weight is exceeded, in order to assure reasonable protection to road surfaces.

The maximum load per centimetre of tire in contact with the road is fixed at 150 kilos. Steel tires are forbidden for all types of automobiles, but a period of five years is allowed to make transformations. Strakes cannot be used on the wheels of any road vehicles. The maximum overall width of vehicles is fixed at 98 in., and wheel hubs must not project.

## European Factories Develop Small Cars

### Paris Show to Exemplify Drift from High Operating Cost Vehicle

PARIS, June 18 (By Mail)—Average piston displacement will show a considerable drop on the automobiles to be presented to the public at the Paris automobile show, opening Oct. 5. At the present time the average piston displacement of French automobiles is in the neighborhood of 183 cu. in. if considered on the basis of number of types produced. If actual production figures are considered, however, the average piston displacement drops to about 130 in., for the cars built in the greatest quantities are those with small engines.

The coming drop in size is due to the decision of several important firms having hitherto built only large and medium size cars to put smaller models on the market. This move has been rendered necessary by the changing economic conditions and the desire of the public to possess cars which will be less costly to maintain. It does not imply a reduction in quality, but the building of cars which will be economical to operate because of their low gasoline consumption, smaller tire costs, and reduced taxation.

There is a feeling even among users who have the means to operate a big car that it is economical to maintain two machines—the big one being used for long distance travel when a full load is carried, and the small car getting general and about-town service. The economies in gasoline and tires more than compensate for the taxes on two cars.

Among those who are stepping into the small car field is Delage with a four-cylinder, 10 hp. model fitted with front wheel brakes. When he entered the automobile business, Delage specialized on a car of this size, but during the war he transferred to a big six-cylinder luxury type. This model is being continued, but the new model will be a four-cylinder type of 2.7 in. bore. Delage has no intention of invading the cheap, big production field, but is presenting his smaller type for those clients who feel that it is uneconomical to use a 40 hp. six-cylinder model for town service and short distance trips.

#### Darracq to Make New Line

Darracq, whose present models are an eight-cylinder of 2.9 in. bore and a four-cylinder of 3.3 in. bore, will probably drop the latter next year when they put on the market a new 10 hp. four-cylinder type. The line will thus consist of a powerful luxury type car and an economical 10 hp. four-passenger automobile. A similar change is contemplated by Lancia, one of the most reputable makers on the Italian market, who will maintain his present big four and supplement it with a popular high grade four.

Sunbeam, in England, has a 10 hp. four-cylinder car under construction, and the Austin factory is also preparing an automobile of the same size and power. Panhard, whose smallest model at present has a four-cylinder engine of 2.8 in. bore, is contemplating the production of a still smaller type. The three biggest producers on the Continent of Europe—Fiat, Renault and Citroen—will not make any important change, for these firms already build cars with the smallest engine possible on a full size four-passenger automobile, the piston bores being 2½ in. for Fiat, 2.9 in. for Renault, and 2½ in. for Citroen.

#### Voisin to Be Only "12"

With the exception of Voisin, who has a big 12-cylinder high grade car under test, there are no indications that new luxury models will be presented at the Paris show. Even if the 12-cylinder Voisin is offered for sale it will not interfere with the output of the present four-cylinder, sleeve valve engine of 3.7 in. bore.

Two or three of the leading French makers are experimenting with cycle cars, but it is too early to state whether these will be placed on the market next year or not. French conditions call for a machine which will be economical, and which at the same time can maintain a high average over fast and rather rough roads. It is recognized that the problem of producing a two-passenger machine with an engine of not more than 67 cu. in., weighing 770 lb. complete, is not an easy one, and there is a certain amount of hesitation in placing on the market anything which is not mechanically satisfactory.

Up to the present the cycle car has remained in the hands of a limited group of very small firms who do not possess the means to produce in quantities. Experiments are now being carried out by several of the big producers.

## California Rail Board Opens Car Department

SACRAMENTO, CAL., July 1—The California State Railroad Commission announces the establishment of an automobile department, due to the great growth of freight and passenger transportation by automotive vehicles in this State. The department will be under the direction of Charles A. Bock, and headquarters will be in the offices of the railroad commission. According to the announcement, the new department will be responsible for all detail work connected with the automobile stage and truck industries in California; will care for all informal as well as official correspondence, complaints and suggestions; will maintain up-to-date timetables and schedules of all automotive services in the State; will handle applications which can be disposed of by ex-parte orders; handle and assign public hearings, answer all verbal inquiries, and in general, assume responsibility to the State Railroad Commission for all work in connection with the operation of motor stages and trucks.

## American Cars Open Route Across Andes

### First Trip Between Argentine and Chilean Capitals Is Successfully Negotiated

NEW YORK, July 1—The long awaited completion of a transcontinental automobile trip across South America, from Argentina to Chile, has at last been realized. Under the auspices of newspapers of Buenos Aires, the capital of Argentina, and of Santiago, the capital of Chile, with the Automovil Club Argentino, likewise of Buenos Aires, two American cars recently completed the long trip between the two countries, and the Argentine club sees in the result a great boost to road improvement and to touring generally.

Information received by *El Automovil Americano*, the Spanish automotive publication of the Class Journal Co., shows that the two cars were forced to go far south to find a crossing over the Andes. The actual start of the trip to Santiago was made from Bahia Blanca, Argentina, some 700 kilometers south of Buenos Aires. From Bahia Blanca, the cars proceeded westward, crossing the Andes to the south of Chillan, proceeding from there to Santiago by way of Talca. Twelve days were required to make the trip, and the only really serious difficulty was found in crossing the mountains. One of the cars was threatened with being upset when ascending a steep mountain grade, but by quick action the driver was able to prevent serious damage, and the car continued its run without loss of time.

The pathfinders were welcomed by crowds at every city and a reception was tendered them by President Allesandri of Chile at Santiago. For the return trip, which was to be made to Buenos Aires, the route picked to Bahia Blanca and then northward to the Argentine capital, was 2630 kilometers (about 1600 miles).

"The first trial run has brought the matter of road construction and improvement to the attention of all leading persons in both countries," the Argentine club comments. "It will help more than anything else to promote highway building and will be a big influence in fostering the idea of long distance touring in this country."

#### TRACTORS DO ALL WORK

INDIANAPOLIS, July 1—Tractor men in Indianapolis are interested in a test field of corn just south of the city. The owner of the field is attempting to cultivate the entire crop with motive power. Tractors were used to break the ground to prepare the soil for planting, and for cultivation up to the present time. Yesterday, with the corn three feet high, a tractor was used to draw the twelve-shovel two-row cultivator. The corn sprang up behind the power machinery unharmed, demonstrating the practicality of tractors for this work.

## High Tariffs Hurt Exports to Spain

### Splendid Opportunities for American Makers Seen With Revision on Equitable Basis

WASHINGTON, July 2—The American automobile industry in Spain has been almost killed by high tariff duties. Commercial Attache Charles H. Cunningham, stationed at Madrid, reports that at the present time it is necessary to pay a duty of approximately 14 pesetas per kilo on automobiles and motorcycles. This includes 45 per cent surtax for gold.

During the past 18 months the Spanish market has been rather well supplied with second-hand automobiles, both touring cars and trucks, which were left over from the supplies in France. It is reported that aside from these 5000 used automobile trucks have come from Germany and Belgium, though this figure is questioned considerably. In any event, the automobile imports into Spain are quite badly paralyzed by the heavy import duties which were imposed on Dec. 1, 1920. Practically no orders are being placed except for spare parts and a large number of cancellations have been made.

The tariff and exchange situation also has given the French a great advantage in the automobile tire market in Spain, which had been more or less in the control of American manufacturers. The American market also has been greatly harmed, according to Cunningham, by the vast number of irresponsible tire concerns which have sent their products into Spain during the last four years. Some have sold their tires in job lots. Some have sent tires originally destined for use in France. A large number have placed agencies with small concerns doing a business of 40 or 50 tires a month. These concerns cannot sell as cheaply as the larger ones, are unable to guarantee their goods and American tire companies which are being represented by them frequently have to bear the brunt of having their reputations sullied by the practice of their agents.

#### Recommend Combination

The commercial attache recommends combination as a remedy, through some sort of consolidation similar to the United States Steel Consolidated Corp. under the Webb-Pomerene act, which would maintain an American in Spain to supervise the sale of the products and keep a watchful eye over distribution and at the same time support and stimulate their selling desire. Complaint also is made that American makers of automobiles and tires do not grant as liberal sales commissions as do the French and Germans.

Discussing in detail the situation as it relates to automobiles, it is pointed out that, although supposedly the tariff duties would weigh with equal burden upon all importers, as a matter of fact

this is not true. The Ford plant in Cadiz, which was putting together 700 cars a month and employing 200 men, has closed down. It is impossible to sell the more expensive cars of the Packard type for less than 65,000 pesetas, while the Hispano-Suiza and the Fiat of the same reputation and caliber can be sold at 45,000 pesetas, including the body.

The duty paid on automobiles of the Cadillac and Packard types has been increased from 2000 to about 10,000 pesetas, rendering the sales of such cars almost impossible. It is not possible that the Spanish industry will be able for a long time to meet this market's requirements. Accordingly, the new tariff is a protection against American automobiles, the sales of which necessitated the employment of hundreds of people throughout the country, who are now finding their business ruined unless active steps are taken to remedy the situation.

#### Importers Make Protest

Protests have been made by a number of automobile importers and associations of importers, and it is the common belief that the Spanish government is aware that the Spanish industry is not sufficient to supply the home demand and that the new tariff will bring about a reduction in the duties as established last December.

The general policy of automobile dealers in Spain at the present time with respect to new business is one of watchful waiting. However, in the meantime, it is explained, a typical American industry excelling that of other countries is entirely paralyzed, and should this condition continue there will be considerable financial distress among friends of American manufacturers and the former will be forced to turn to the representations of German and French cars against their will.

The only plant in Spain that seems to be doing a purely Spanish automobile manufacturing business is the Hispano-Suiza of Barcelona and Guadalajara. It is stated that the total capital invested in this enterprise is about 50,000,000 pesetas. During the war the Hispano-Suiza Co. sacrificed its automobile production for the making of airplane engines. 75 per cent of which were sold to the allies. There is said to be at present about 1600 men at work in these plants. They earn all the way from 8 to 15 pesetas a day in wages. A large part of the specialized machinery utilized came from the United States and England and the American machinery is said to have given entire satisfaction. At the present time Hispano-Suiza is engaged in work on 12 different types of car chassis and engines.

#### All Work Done at Plant

It is stated that all of the work on all of the parts except the wheels for the touring car is done in the Hispano-Suiza plant. Truck wheels are also made and the wire wheels utilized on the touring car and passenger car chassis are of the Rudge-Whitworth type made in England. The output of the Hispano-Suiza plant

(Continued on page 47)

## Dealers to Outline Contractual Views

### N. A. C. C. and N. A. D. A. Conferees Approach Basis for New Business Relations

DETROIT, July 2—Efforts looking to the establishment of close co-operation between factory executives and dealers are beginning to breed results. Committees representing the National Automobile Chamber of Commerce and the National Automobile Dealers' Association expressed themselves highly pleased with the results of their second conference held at the Detroit Athletic Club yesterday. The conference was continued to July 12, when the committees will meet in Buffalo.

A formal draft of the position of dealers on matters under discussion will be presented at the Buffalo meeting by Harry G. Moock, general manager of the dealers' association. Following yesterday's meeting he expressed confidence that action favorable to the industry generally would be taken at that time.

Developments at yesterday's meeting were practical agreements to the effect that cancellations of contract in the future shall be only on recognized factory authority rather than at the hands of various persons as now is possible. That persons suffering cancellations should have opportunity for appeal also seemed to carry weight with many of the conferees. There also seemed to be unanimity of opinion that contracts should be made dependent on performance rather than subject to renewal at definite dates.

The question of the disposition of cars in cases of contract cancellation brought forth considerable discussion but no definite action was indicated.

General Manager Alfred Reeves of the N. A. C. C. expressed gratification after the meeting at the harmony which characterized the proceedings and said it gave assurance that all problems now being threshed out would be settled.

### Reports on N.I.V.A. Contest at Fargo Available July 11

FARGO, N. D., July 5—The National Demonstration and Show Committee of the N. I. V. A. has issued the following statement in regard to the tractor and horse contest staged here.

"Data secured in connection with the Fargo Farming Demonstration will not be complete until the horse outfits have finished their work and the records of all tractors and horses have been carefully checked. No information on this subject will be given out until July 11, on which date the National Committee will meet again in Chicago.

"Results of the Fargo Demonstration will be discussed at that time with a view to deciding future demonstrations. Information and the data regarding the Fargo demonstration will be made public."

## Babson Would Keep Executives on Job

Says Market Speculation Hurts Car Development—Predicts Coal Dust as New Fuel

TOLEDO, July 6—Roger Babson, economist, who visited Toledo to make several addresses to business men and to study the automobile industry here, declared his studies had led him to the belief that the best showing is going to be made in the automobile industry by the companies which absolutely bar the officers and employees from automobile and other stock market speculations.

"Automobile officials have paid too much attention to the stock market and not enough heed to the quality of the cars they were turning out," he declared.

Babson said the swing in automotive channels was toward not only the use of light models but the manufacture and use of lighter machines than are now being driven.

He pointed to two lines of experiment that were fundamental to the automotive industry, in his opinion. One was the use of bituminous coal dust for fuel and the other was the development of cottonoid and paperoid bodies for lighter construction.

"I happen to be conversant with experiments now being made by several automobile manufacturers in the use of bituminous coal dust as fuel for automobiles instead of gasoline," said Babson, "and the result of the experiments so far indicates that within a few years gasoline at high prices will no longer be used as motive power for automobiles.

"The coal dust will be blown into the carburetor of the car and burn with sufficient intensity to provide all the heat and power necessary for the operation of the machine. Fifty cents' worth of coal dust thus utilized will carry a car the same distance that five dollars' worth of gasoline now carries it. This decrease in the cost of operating an automobile will greatly increase the use of automobiles.

### Plan Lighter Automobiles

"I have witnessed experiments with cars whose bodies are made out of a combination of formaldehyde, glue and cotton, a material that has come to be known as cottonoid. Similar material may be made out of paper as one of the three ingredients, so to speak, instead of cotton. So we are to have automobiles with cottonoid or paperoid bodies, making the car much lighter, and more durable and cheaper.

"I saw an experiment made with a car that had a cottonoid fender. The car was made to collide head on with a brick wall. The cottonoid fender gave in like rubber and rebounded the car like a rubber ball. Such a fender does not break or bend like steel, but has resiliency and sufficient strength to protect the machine in collision.

"It is not the initial cost of a car that

keeps down the sales of automobiles, but the upkeep. With lighter bodies made of the new material and with better tires—and they are coming, too—the increase in the sales and the use of automobiles will be enormous, for the initial price will be lower and the upkeep much less expensive."

Babson believes that the present center of manufacture of motor cars is best adapted to their production and that the territory in the vicinity of Detroit, Cleveland and Toledo will continue to be the great automotive district.

## Willys Takes Message of Cheer to Dealers

PHILADELPHIA, July 2—John N. Willys, president of the Willys-Overland Co., introduced by Harry B. Harper, president of the Overland Harper Co., addressed a meeting of Overland Harper dealers at the headquarters of the local company, Forty-second and Chestnut streets, bringing a message of optimism to the trade.

Among the things Mr. Willys said were:

"Work is a great thing. It will accomplish anything. We have weathered the storm and now it is plain sailing ahead. We are back to the production of 400 cars a day and by next month we expect to increase this to 600 cars. Our organization is the best we ever had, and so are the shopmen."

"June was good," said H. B. Harper, "but it isn't going to be a patch on what we are going to do in July. Our product is right, our prices are right, and this response of the buying public proves that better business, increased sales and a big future await us."

## Rush of Truck Sales Reported in South

BIRMINGHAM, ALA., July 6—With the renewal of activity in the lumber business and all other building material businesses in Birmingham, the sales of trucks have shown a marked increase, according to local automobile dealers.

The demand for new trucks has increased during the month of June so rapidly that all orders placed by local building material dealers could not be filed on schedule time. Many of the most urgent buyers were compelled to wait for delayed shipments to get their new equipment.

"Receipts on repairs at the garage would indicate that the number of cars is increasing," said P. Y. Whitman, of Whitman's Fifth Avenue Garage.

"Buicks are selling faster than we can order them in," said Donald Drennen of the Birmingham Motors Co.

"Dealers who are members of our organization are very optimistic over the outlook for the coming year in the automobile business," said James P. Dobbins, secretary of the Birmingham Automobile Club. "They are anticipating a banner sales year for new cars. Business was light for a time, but the automobile line is picking up now."

## Denby Creditors Plan Funding Firm's Debt

Committee Is Named to Work Out Refinancing—Truck Prices Reduced

DETROIT, July 2.—Creditors of the Denby Motor Truck Co., at a meeting yesterday, named a special committee of five, headed by J. H. Johnson, president of the Peninsular State Bank, to formulate plans for presentation July 12 for funding the company's indebtedness. C. A. Ailes, a member of the creditors' committee which has been operating the plant for the last year, said that while the plant is free of all bonded indebtedness the plan in view is to ask creditors to accept part payment in bonds and the balance in stock in order that the company's statement may be put on a bankable basis. It also is proposed to issue bonds for about \$100,000 as class A bonds to furnish working capital.

In addition to Johnson, the committee is composed of J. M. Burns and B. J. Lincoln, Detroit attorneys representing creditors, O. W. Myers, district credit manager of the Goodyear Tire & Rubber Co. and W. P. Fuller of Fuller & Sons Co., Kalamazoo. The Denby company will continue in operation. It has debts of about \$650,000 but is solvent and assured of success if given opportunity to work out of its present difficulty, said Ailes.

Announcement was made by the Denby company today of price reductions effective immediately. The three-quarter-ton and 1-ton speedster will sell for \$1,625; the 1½-ton for \$2,300; the 2-ton for \$2,600; the 3-ton for \$3,300; the 4-ton for \$4,200; the 5-ton for \$4,850, and the 7-ton for \$5,500. This is a reduction of \$200 on the 2-ton, \$300 on the 3-ton, \$400 on the 4-ton, \$500 on the 5-ton and \$700 on the 7-ton.

The light trucks are equipped with pneumatic tires and the others with solids. All models except the speedster are equipped with bumpers.

## Federal Trade Board Accuses Rubber Firm

WASHINGTON, July 5—Issuance of a complaint against the Diamond Holfast Rubber Co. of Atlanta, Ga., has been announced by the Federal Trade Commission on allegation of unfair competition in the manufacture and sale of automobile accessories and repair materials in interstate commerce. It is claimed that this company marketed its products in such a way as to pass them off as the products of the Diamond Rubber Co., a subsidiary of the Goodrich. It is further alleged that the respondent sold its products in containers with labels which featured the word "Diamond" and so closely resembled the labels of the Diamond Rubber Co. The company has 30 days to file an answer.

# 122 Inch Engines for 1923 Classic

## Indianapolis Fixes Lower Displacement

### Limitations Below Specifications of Any Car Now in Quantity Production Here

INDIANAPOLIS, July 7—T. E. Myers, secretary and manager of the Indianapolis Motor Speedway Co., has announced that the 1923 race on the famous track will be for cars powered with engines having a maximum piston displacement of 122 cu. in. Translated into European terms this is two litres. The 1922 500-mile race, the tenth annual event, will be for three litre cars, or engines of 183 cu. in., the same size as the 1920 and 1921 races.

This is the fifth time that the Indianapolis track has reduced the engine sizes for the cars competing in the five-century, considered by some the classic of all the world's annual speed events. Off-hand such reductions would be expected to result in decreasing the speed of the cars, but such has not proven to be the case. Automotive engineers have thus far been able to obtain more speed in fact by designing smaller bore and higher speed engines.

The 1923 race will have engines smaller than anything now built in quantity in America. The smallest engined car to-day in large production is a four cylinder, measuring 143.1. The Ford engine is near the 183 maximum. Reductions in the size of racing engines have frequently been reflected later in the stock production of the American makers. The "crucible of racing" has proved to the satisfaction of the engineers that fuel economy could be effected by reducing the engine sizes. In the last race the average car's mileage was ten to the gallon. Two years hence it should pass the twelve mile mark.

The efficiency of the two litre engine was demonstrated recently in the French economy Grand Prix at LeMans, where a De Dion Bouton of this class showed 49.09 miles to the gallon in a stock test.

Except for the announcement of the engine limitations no other specifications for cars admitted to the race have yet been made public.

## Overland Goes Over Expected June Output

TOLEDO, July 5—With a big drive through to the last day of June, the Willys-Overland plant here went 37 cars over its schedule for the month for a total production of 8537 cars for the month. On June 2 the schedule was fixed at 3500, but the increased volume

of sales caused this to be boosted to 8500 for the month. Purchasing agents, production men and others struggled through the hot weather to "come through," and the record was made.

The July production will be increased 50 per cent and, according to appearances, August will be a busy month at the plant. Some departments at the factory here have been forced to put on three eight-hour shifts this month. The big month was the first real test of the new production system put into effect by Vice-Presidents Walter Chrysler and Charles B. Wilson.

## Reo Motors Down for Two Weeks' Vacation

LANSING, MICH., July 2—All departments of the Reo Motor Car Co. except the service and repair closed to-day for two weeks. The simultaneous vacation plan has been under consideration for some time. Opposition to the plan was overcome by the argument that present business conditions made the opportunity for trying it out most propitious. H. C. Teel, general superintendent and an ardent advocate of the plan, said it was the intention to drop all work wherever possible even in the repair and service departments and take two weeks rest in the hope of eradicating all feeling of apprehension regarding market conditions.

## Dodge Orders Assure Production to 1922

DETROIT, July 2—The announcement was made to-day by Dodge Bros. through President Haynes that production would be maintained at capacity for the remainder of the year. Production at the Dodge plant since the price cut has been increasing daily and is now around the 600 mark. That output, Haynes said, would be continued throughout the year. This assertion is based on present orders and prospective demands.

Haynes said dealers' stocks were exhausted and that cars rapidly are going into the hands of consumers. The factory is far behind on orders.

### TO PICK A. A. A. SECRETARY

NEW YORK, July 6—The Executive Committee of the American Automobile Association at a regular meeting at the Hotel Commodore to-day named a committee of three—George Diehl, president; David Jamison, past president, and Horace Bonnell, treasurer—giving it authority to appoint a successor to A. G. Batchelder, the late executive secretary who was killed in an airplane accident near Langley Field. The committee will announce its selection soon.

## Franklin Sets Marks on 20th Anniversary

### Ships 138 Cars in Day and Completes Biggest June in History

SYRACUSE, July 2—Three leading events in the history of the Franklin Automobile Co. were celebrated this week—two of them records for shipments and sales, established on the same day, June 30, and the third, the twentieth anniversary of the company, July 1.

The Franklin company shipped 138 cars Thursday, the biggest shipment for one day it ever made. The last previous record was made on Dec. 31, when 110 cars were shipped.

On the same day Franklin dealers throughout the country sold 132 cars, which establishes a record, and helped make the company's business for the month the largest for June in its history. Last year was considered a banner year for car orders, but four more cars were shipped last month than in June, 1920, the total being 1031.

In celebration of the anniversary the company officials and employees held a parade, headed by the Franklin band of 35 pieces. A feature of the procession was the first Franklin car ever sold, run on its own power. In this car rode a man and woman dressed in the styles of twenty years ago. John Wilkinson, who built the car, rode just behind it in a 1921 Franklin sedan.

In 1901 Wilkinson, who is now vice-president and consulting engineer of the Franklin company, started work for H. H. Franklin and A. D. Brown, now of the Brown-Lipe-Chapin Co., under the name of Brown & Franklin Co. The first car was turned out March 3 of the following year. This car had four elliptic springs, a wood frame instead of steel, and an air-cooled engine, features which have endured in Franklin cars right through to the 1921 models.

Thirteen cars were turned out in 1902, of which eleven were sold. Sixty-five persons were employed the first year, and in the twenty years since then the force of employees has grown to 3200.

## Car Reductions Swell Chicago Sales Totals

CHICAGO, July 6—In all lines of cars which have reduced prices there was a very decided improvement in sales for the month of June as compared with May and April. In many cases reports are to the effect that record sales are the result of June efforts. Automobile Row in Chicago appears to be busier than in months.

## Lower Prices Reduce Export Trade Totals

Statistics Show Wide Difference in Wages Abroad and in Factories Here

(Continued from page 41)

1920, the statistics show that workers in automobile, carriage and airplane factories in 1914 received \$17.06; in 1916, \$18.86; in 1918, \$23.39; in 1919, \$27.49 and in 1920, \$32.51. The industrial survey by the Department of Labor Statistics, comprising 28 states in 1920, showed that the average weekly earnings in the United States for factory machine workers, machine molders, etc., was \$29.70 for 49.8 actual hours of work. Pattern makers' actual earnings for 48 hours work averaged \$43.73; rough carpenters and patternmakers' helpers, \$26.08; bench molders, \$28.06; core makers, first class, \$31.36, actual average earnings; second class core makers, \$26.52; laborers, \$22.22, actual average earnings.

These figures show the advantage which producers of foreign cars have over American automobile manufacturers and exporters.

In England, the average earnings for common laborers in the iron and steel industry in 1921, per 47-hour week, amounted to \$12.52, under the present rate of exchange. In France, the mean rate per day of eight hours for metal workers, in 1921, was considerably below the average rate in this country. For illustration, fitters in automobile plants received an average of \$1.72 per day; fitters on chassis, \$1.47; automobile electricians, \$1.34; countersinkers for automobiles, \$1.62; ordinary laborers in automobile factories \$1.04, and wood working machinists on automobiles, \$1.32; pattern makers for automobiles, \$2.18, and turners for automobiles, \$1.81.

### Must Revive Foreign Trade

Of the utmost significance is the fact that the Federal Reserve Board believes that we cannot reasonably expect a complete recovery in domestic trade without having a somewhat corresponding advance in foreign business. They insist that foreign trade is needed as a stabilizer of values, besides being essential as the means of insuring full demand for goods and complete activity for productive energies. The Board believes that the change in the balance of trade has been brought about, not so much through increase in the value of imports, but rather by decline in the value of exports. In fact, the value of exports, although showing some increase over the very low figures of January of this year, is still in value only half the figure for April 1920.

Price declines have naturally been responsible to a considerable extent for the reduction in values during recent months. For this reason the foreign trade index of the Federal Reserve Board is particularly significant in interpreting the volume of trade as com-

pared with previous months. This shows that while the volume of exports has been shrinking steadily since the latter part of 1920, the physical volume of imports has been increasing much more rapidly than the value figures indicate, owing to reductions in prices. To the extent that this index is representative of our foreign trade as a whole, the conclusion is justified that exports in April had declined to about the same volume as in April 1913, while imports were reaching this country in nearly double the quantity of the corresponding pre-war month. So far as individual commodities are concerned, the increased volume of imports is well distributed among the several classes of goods.

## France Soon to Market New Gasoline Mixtures

PARIS, June 18 (By-Mail)—Gasoline, alcohol, benzol mixtures for automobile use are likely to find a place shortly on the French market. When the next lot of German benzol to be delivered under the terms of the Peace Treaty is received, the French stocks will amount to 2500 tons. An attempt to dispose of this fuel to private interests met with no success, for one of the conditions was that the purchasers should also buy an equal quantity of Government alcohol to be mixed with the benzol. As dealers will not accept this, the Government doubtless will be obliged to make a gasoline-alcohol-benzol mixture and place it on the market. It is impossible to delay any longer for no more storage space exists for the accumulating stocks.

To reduce the alcohol stocks, a proposal has been made by the Mining Commission that no gasoline shall be allowed to be sold unless it contains at least 10 per cent alcohol. As alcohol will not dissolve in gasoline, a solvent would have to be used, and among those recommended are gasoline 80 per cent, alcohol 15 per cent, and castor oil 5 per cent, or gasoline 80 per cent, alcohol 10 per cent, and ether 10 per cent.

Alcohol manufacturers have carried out tests with a mixture composed of 30 per cent alcohol at 90 degrees, 11 per cent benzol, and 59 per cent gasoline, which they declare gives a saving of about 2 per cent compared with straight gasoline. Professor Letombe and Captain Mau'ere have experimented with a stock Renault, with normal carburetor adjustment, using a mixture known as E. H. A., comprising 65 per cent alcohol, 10 per cent ether and 25 per cent gasoline of benzol.

### HARPER-BEAN GAINS TIME

LONDON, June 17 (By Mail)—The court has again heard the petition of G. Johnston, furnisher of upholstering and body trade materials, one of whose specialties is the American leather substitute called "Duratex," for an order for the compulsory winding up of the Harper-Bean company. It was adjourned on the statement that a plan is being prepared by a creditors' committee. Output is continuing steadily.

## Hoover Pushes Plan to Expand Commerce

Industrial Groupings Under Way to Meet Individual Needs—Appropriations Made

WASHINGTON, July 2—With an appropriation of \$250,000 at hand, Secretary of Commerce Hoover is ready to undertake the development of American foreign trade through the reorganization of the Bureau of Foreign and Domestic Commerce. He has definite plans for the expenditure of this amount in order to boost sales of automobiles and other commodities on the foreign markets. He has already completed the organization of several industrial groups including textiles, chemicals, coal and oil, leather products and foodstuffs. The automotive group will be decided upon within a few days.

It was the original intention of Secretary Hoover to establish twelve industrial groups but it has not been definitely determined as to the number that will be set up and no specific provision is made by Congress as to the groups organized. These groups will carry the same parallel groupings that apply to the Bureau of Standards and the Bureau of the Census.

The Bureau of Standards also was given \$250,000 of the appropriation of one million dollars for the Bureau of Census, for the continuation of investigation of structural materials for which \$50,000 is allowed; for technical investigation in co-operation with industries upon fundamental problems involved in industrial development following the war, with a view to assisting in permanent establishment of the new industries developed during the war, including personal services of the District of Columbia and elsewhere, for which \$100,000 was allowed, and for co-operation of the Bureau of Standards with Government departments, engineers and manufacturers, with regard to standardization and testing of instruments, equipment, tools, etc., for which \$100,000 is allowed.

### Needs Two New Assistants

The Hoover plan for groupings calls for two additional assistant directors, making four in all, who will constitute the heads of division and assistants to co-operate with service committees selected in the various industries.

Experts will be assigned to the automotive field to make special investigations into particular trade conditions abroad. Information relating to vital facts of value to industries in this country will be collected abroad, adequately prepared and distributed to show the trend of conditions on foreign markets. Secretary Hoover is convinced that co-operation of industry with the Government is essential to check the growing tendency in foreign countries to consolidate for militant export purposes.

## High Tariffs Hurt Exports to Spain

### Output at Hispano-Suiza Plant About 15 Units Each Month

(Continued from page 43)

in Barcelona at present is said to be 100 units per month. It also is stated that orders are booked up for a year in advance and dealers usually tell prospective buyers that it will be necessary to wait a year ahead.

It is evident that the Hispano-Suiza people are counting on an extension of output in the future as they are enlarging their factory and installing more extensive and modern machinery. Stress is laid on the fact that this is the only automobile plant in Spain where all parts from engines to truck bodies are made. There is also an Hispano-Suiza plant for the manufacture of trucks in Guadalajara. It is claimed that the output at present is not more than 15 units per month.

Neither the Renault nor the Fiat, being marketed in Spain, is said to be performing up to former standards. The Germans have recently imported into Santander a light car, the Simpson, selling at 10,000 pesetas. The Germans are also selling an apparently new truck, made by the N. A. G. Co., at 32,000 pesetas. This company also is selling in Spain a 35-hp. type C limousine at 37,000 pesetas, and a smaller car, four cylinder, of 20 hp., at 28,000 pesetas.

Relating to the tire situation, Cunningham said he had been informed that the French give 25 per cent commissions on sales prices. In view of the fact that more costs are borne by dealers representing American cars than the French, freight, commission, pilferage, interior freight, etc., it seems that American concerns should give more liberal instead of less liberal terms.

The French, of course, enjoy a great car advantage in that they are able to run their cars into Spain instead of shipping them by boat or rail. The commission of English cars is usually from 15 to 20 per cent. Some American car dealers, it is said, give better commissions. The disadvantage to American sales is apparent when it is remembered that in many of these cases agents who sell American cars also sell French or German makes, and it is naturally to their interest to sell the car which will yield them the largest commission.

#### Payment Terms Too Rigid

There is quite a general complaint against the rigid terms of payment demanded by American automobile makers. It is said that the usual terms now are cash against documents or a guaranteed credit at a local bank for siting fund in New York when the automobiles are shipped. This, the dealers state, is not sufficient to compete with the French, who are now granting 90 days after the cars arrive in the dealers' hands, and the

larger makers of France are even willing to give an extension of time.

Another criticism which is made of American tire and automobile manufacturers is that they do not assist in bearing the burden of advertising.

Early in March Mr. Cunningham, the commercial attache at Madrid, cabled the Bureau of Foreign and Domestic Commerce that a Royal Decree would be issued about March 20 lowering the present high duties. This was to be done, he declared, in order to restore the industry to something like its previous magnitude, as it was realized that the new rates were too high. However, a few days later, on March 13, he cabled again that internal conditions in Spain were such that the decree would be postponed until a later date. No further information concerning the subject has been received at New York, but the hope was expressed that the duties would shortly be decreased.

## Tire and Rim Men Want Change in Disk Wheel

NEW YORK, July 6—The Tire and Rim Association is endeavoring to induce disk wheel manufacturers to design their wheels in such a manner that tire valves will be accessible from the outside of the wheel. It is thought that because of the necessity of inflating disk wheel tires from the inside, tires have suffered through under-inflation.

The regular semi-annual meeting of the Tire and Rim Association will be held at its Cleveland headquarters July 27.

Members of the Tire Manufacturers' Division have been requested to advise the association of their views respecting the desirability of quarterly meetings being held in addition to the regular monthly meetings of its executive committee.

## Cadenhead Rim Nears Early Production Date

BIRMINGHAM, ALA., July 2—The Cadenhead Auto Rim Co., Inc., has completed its 10-inch rolling mill, or guide mill for the patented rim making works, and the machinery is being placed. It is expected operation will be under way in July, some delay having been encountered. The first date set for the beginning of operations was in May. The patented rim will be manufactured complete in the local plant, which is located at Tarrant City, a suburb of Birmingham. The steel billets for the rolling mill will be purchased in Birmingham and worked up in the plant.

The rolling mill is 60 x 120 ft., and the rim plant, 60 x 160 ft. It will have a capacity of 3000 rims per day. Rims for both passenger automobiles and trucks will be manufactured. Between 40 and 45 men will be employed in the first unit of the plant, and as soon as the first one is well under operation work will be started on another.

## METAL MARKETS

It is obviously by amicable arrangement that market leadership has for the time being come to be vested in the "Independent." Announcement by the chief "Independent" interest of a downward revision in prices, which was made on Tuesday, was followed by a similar proclamation issued by the Corporation on Wednesday. The Corporation's monthly unfilled tonnage statement, which will be issued on Saturday, will undoubtedly reveal a further shrinkage in its backlog of orders. The cuts announced are nothing more than a process of clothing what for several weeks have been market prices in the garb of official quotations. The Corporation has not been selling any steel at its official prices for some time and has been meeting competition wherever any desirable business offered. The steel market has never been more demoralized than it has been in the past few weeks, and it remains to be seen whether these revisions in prices will raise its morale. It is amazing how quickly the lustre of a set of prices wears off once it becomes obsolete in practice. While the Corporation adhered to the Industrial Board's schedule and "Independents" exacted fat premiums, every steel buyer in the country knew the Corporation's prices by heart, whereas its late official prices have been all but forgotten. Step by step, however, the market is coming nearer to a return of stabilization, and as demand for the present is negligible buyers can well await further signs of such stabilization, meanwhile covering their requirements by less than carload lots, which appears to be about all the business in sight. Producers are giving their principal attention to further downward adjustment of wage scales. At least one of the "Independents" has fallen away from the Amalgamated Association and is seemingly prepared to go on an open shop basis. Others are continuing further negotiations with the union at a meeting in Columbus, Ohio, this week. The union sheet mills are closed. The concessions asked by the mills are of minor importance and pertain to efficiency rather than to wages.

**Pig Iron.**—Automotive foundries, if buying at all, confine themselves to small tonnages, many of which they are able to pick up at concessions in the resale market.

**Steel.**—Were it not for a desire on the part of many mills to afford their employees an opportunity to work at least part time, they could save money by shutting down. The leading low-priced passenger car maker is said to be buying very little in the way of sheets, but has placed additional orders for bolts and nuts. Prices appear to be absolutely at buyer's mercy.

**Aluminum.**—It would seem that with knowledge of the aluminum tariff recommended by the Ways and Means Committee, 5c. a pound on ingots (as foretold in this column) and 9c. per pound on sheets, somewhat more interest on the part of buyers should develop in the course of the next few weeks. While newspaper opinion leans to the view that there will be a marked difference between the committee's recommendations and the law that will be passed, there will be those who will want to provide against any contingency.

**Magnesium.**—In view of the fact that quite a little magnesium is used in pistons and as an alloy in die-castings, the proposed duty of \$1 a pound is attracting considerable attention.

## FINANCIAL NOTES

International Motor Truck Co. reports sales to June in excess of 2400. This is at the rate of 70 per cent of last year's business. Net quick current assets are in excess of \$20,000,000. Cash is over \$3,500,000, while notes and accounts receivable are in excess of \$5,000,000. Inventories have been reduced more than \$3,000,000 since January and will be reduced still more during the next three months. Commitments for material are very slight and only for current requirements.

Timken-Detroit Axle Co. reports sales running at approximately \$1,200,000 a month. Normal business is about \$35,000,000 annually. Since January 1 inventories have been reduced from \$10,900,000 to about \$9,500,000. Bank loans were cut from \$3,000,000 to \$1,200,000, but \$1,000,000 one year notes were sold.

Kelly-Springfield Tire Co. will pay quarterly dividend of \$2 a share on its 8 per cent preferred stock August 15. A quarterly stock dividend of 3 per cent will be paid on the common stock of the company, in common stock, on August 1.

McCord Mfg. Co., Inc., reports an increase in its cash balance to well over \$500,000, as against \$100,000 in February, 1921. It was said the company had sold a large amount of radiators into which it had put copper costing 24 cents a pound.

Malbohm Motors Co. has been granted a judgment of \$14,000 against the Sandusky Chamber of Commerce as the 1921 installment of \$100,000, the Chamber agreed to pay provided the company moved its plant to Sandusky.

Handley-Knight Co. has had approved by the Michigan Securities Commission its \$200,000 issue of first mortgage 7 per cent convertible gold bonds. They are dated April 1, 1921, and run fifteen years.

Studebaker Corp., with a total production in June over 8000, will give the company the biggest quarter by far it has ever had. Studebaker should top 25,000 cars in the third quarter if present conditions continue.

American Motor Body Co. reports net profits of \$269,457, after interest and Federal taxes, for the period from August 11 to December 31, 1920. Sales during this time amounted to \$8,523,875.

Federal Motor Truck Co. paid a dividend of one-half per cent (5c.) on July 1. The last previous payment was 1 per cent on January 1, 1921.

## INDUSTRIAL NOTES

American Forging & Socket Co., Pontiac, Mich., reports that after several months of idleness, in which the plant was almost wholly inoperative, it is now going strong and experiencing a steadily increasing demand for products. At present operations are about 60 per cent of normal.

C. G. Spring Co., Kalamazoo, Mich., is now working 75 per cent of capacity to keep up on orders for automobile bumpers. Several large contracts have recently been taken on, while the replacement business is growing rapidly.

H. L. Hess Co., Philadelphia, has been appointed representatives for the Mueller Metals Co. of Port Huron, Mich., in Eastern Pennsylvania, Delaware, Maryland and Southern New Jersey.

Alvord Reamer & Tool Co. of Millersburg, Pa., now has branches in the following cities: New York, Philadelphia, Pittsburgh, Cleveland, Detroit, Chicago, Louisville and San Francisco.

Cleveland Tractor Co., Cleveland, has moved its Atlanta office to larger and more pretentious quarters at 254 Peachtree Street. S. A. McGonigal is in charge.

Winton Co. is operating at 30 per cent capacity and orders are gaining, President Winton reports.

Goodyear Tire & Rubber Co. will increase production to 3500 tires a day at the Los Angeles plant.

Greenfield Tap & Dye Corp. four plants at Greenfield, Mass., will be closed until August 1.

New Plea to Creditors  
Made By Oklahoma Firm

MUSKOGEE, OKLA., July 5—The Oklahoma Automobile Manufacturing Co., which asked unsecured creditors early in the year to accept 25 per cent of their claims in full payment, now has notified creditors that it is unable to make good on this offer, but that it is in a position to pay 20 per cent. It is said that by the hardest kind of work the management has raised about \$88,000, but is unable "to raise another dollar." This is sufficient to pay only 20 cents on the dollar. The letter says the receiver is selling no trucks whatever and is unable to collect installment notes taken in payment for trucks. Collections are so small that they are not sufficient to continue operations even on a very small scale. Creditors are informed that if they fail to accept the offer made, the company will be thrown into bankruptcy.

Gorrell Takes Over  
Marmon Sale on Coast

SAN FRANCISCO, July 5—One of the most important announcements made in the automotive trade of northern California in June was that of an almost complete change in the personnel of the local division of the Al. G. Faulkner Co., Marmon distributors for California, Nevada and the Hawaiian Islands. Colonel E. S. Gorrell, formerly in charge of merchandising for Nordyke & Marmon, Indianapolis, becomes manager of the San Francisco branch, and brings with him W. E. ("Bill") Combes as sales manager. Colonel Gorrell, who is a graduate of West Point, began his service in 1914 as a flier in the aviation section of the Signal Corps and finally became chief of staff, A. E. F. He was awarded the Legion of Honor by France, the D. S. C. by England, and the prized Distinguished Service Medal by the American Government. During the spring of 1920, Colonel Gorrell resigned his commission and turned his attention to sales promotion with the Nordyke & Marmon company. His combination of engineering, merchandising and general business experience won for him the San Francisco post.

## BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES by the Guaranty Trust Co., second largest bank in America.

NEW YORK, July 7—While the industrial situation still had a depressed aspect as the half-year closed, the credit situation, as reflected in the bank figures, encouraged the feeling that the basis was being laid for a substantial return to normal conditions. The New York Federal Reserve Bank last week again showed the remarkable improvement which has been characteristic of recent weeks. The ratio of total reserves to deposit and Federal Reserve note liabilities combined increased from 68.9 per cent to 70.7 per cent, the highest since the summer of 1917. The ratio of gold reserves to Federal Reserve notes in circulation, after setting aside 35 per cent against deposit liabilities, increased from 103 per cent to 106.7 per cent. This improvement in the reserve ratio was largely the result of a \$23,341,000 increase in gold reserves, which was in turn largely due to further gold imports.

The Federal Reserve System's ratio of total reserves to deposit and Federal Reserve note liabilities combined increased from 60.4 per cent to 60.8 per cent, the highest since 1918. Gold reserves increased \$11,443,000 and total reserves \$5,453,000. In spite of a decline in bills discounted secured by Government obligations, total discounts increased \$17,599,000. Total bills on hand, however, increased only \$9,712,000, while total earning assets declined \$21,908,000. Total deposits declined \$11,459,000, and Federal Reserve notes in circulation \$4,844,000.

The local call money market took on a slightly firmer tone the latter part of the week. The range for the week was 5 per cent to 6 per cent, as against 5 per cent to 5½ per cent the previous week. On Monday a uniform rate of 5 per cent was quoted, and the following two days 5½ per cent was the renewal rate; but on Thursday and Friday a uniform rate of 6 per cent was quoted. This firmness was due apparently to preparations made for the middle-of-the-year's settlements and to Government withdrawals. The time money market was unchanged at 6½ per cent for 60 and 90 days' and four months' paper, and 6 per cent to 6½ per cent for five and six months' paper. There was a small supply of loanable funds, and quotations remained nominal. The commercial paper market was unchanged.

Business failures for the month of June showed a decline, the number of failures at 1290 being the lowest for any month since November, and compare with 1356 in May, and 1895 in January. They are, however, far above the 674 failures reported for June, 1920. The liabilities involved were also much smaller than for the previous month, the respective figures being \$31,987,313 and \$57,066,471. The liabilities were also the smallest for the current year.

## NEW CAR PRICES

Packard Cuts Prices  
on Cars and Trucks

DETROIT, July 5—New prices on Packard single and twin-six models as now effective, place the single-six coupe and sedan at \$3,750 and \$3,975, reductions respectively from \$4,150 and \$4,250. In the twin-six the open models are reduced from \$6,000 to \$4,850 and the coupe and sedan from \$8,200 and \$8,450 respectively to \$6,600 and \$6,800. The limousine is reduced from \$8,350 to \$6,650, and the chassis from \$5,300 to \$4,200.

On trucks model EC is reduced from \$3,700 to \$3,500, ED from \$4,450 to \$4,100, EF from \$5,550 to \$4,500 and EX from \$4,200 to \$4,000.

Oldsmobile Revisions  
Include All Models

NEW YORK, July 1—Price changes announced on the various models of the Oldsmobile, effective July 2, follow:

	Old Price	New Price
<b>Four-cylinder</b>		
Roadster .....	\$1,445	\$1,325
Touring .....	1,445	1,345
Coupe .....	2,145	1,895
Sedan .....	2,145	2,100
<b>Light 8-cylinder</b>		
Touring .....	1,695	1,725
Coupe .....	2,395	2,225
Sedan .....	2,395	2,425
<b>Big 8-cylinder</b>		
Touring .....	2,100	1,825
Touring 7-passenger ..	2,100	1,875
Sedan .....	3,300	2,775

90-Day Guarantee Given  
By Mack Against Cutting

NEW YORK, July 5—The International Motor Truck Corp., manufacturers of Mack trucks, has decided to give a running guarantee of 90 days to both dealers and purchasers against price reductions. No time limit has been set upon the period during which this guarantee will be given, but it can be revoked by the company at any time. All purchasers of trucks in the meantime will be guaranteed except where trade-ins are involved.

## CHAMPION MOTORS MAKES CUT

PHILADELPHIA, July 5—The Champion Motors Corp. announces reductions in the prices of its various models. The special touring car is reduced from \$1,595 to \$1,395; the Champion "tourist" from \$1,250 to \$1,095, and the commercial car to \$1,325.

## WOLVERINE TRUCKS CUT

DETROIT, July 1—In conjunction with the announcement of a new line of trucks, the American Commercial Car Co., manufacturers of the Wolverine truck, have reduced prices on the entire

line from \$50 to \$115. The new line will take the place of the former models, and while substantially the same, will embrace new and distinctive features. The new prices are: 1-ton \$2,125, formerly \$2,240; 1½-ton \$2,375, was \$2,465; 2-ton \$2,640, was \$2,750; 2½-ton \$3,425, was \$3,475, and 3½-ton \$4,100, was \$4,150.

## OAKLAND MAKES SECOND CUT

DETROIT, July 6—Prices on the Oakland roadster and the coupe and sedan were reduced to-day by the Oakland Motor Car Co., the reduction being the second announced by the company since May. The new roadster price is \$1,095, a reduction from \$1,145. The coupe is priced at \$1,625 and the sedan at \$1,725, both formerly being \$1,815. The touring car, which was placed at \$1,145 in the May reduction, remains at that price.

## EXCELSIOR CUTS PRICES

CHICAGO, July 2—The Excelsior Motor Mfg. & Supply Co. announces new prices on Henderson and Excelsior motorcycles. The electric equipped Excelsior is reduced from \$480 to \$400 and the electric equipped 4-cylinder Henderson from \$585 to \$485.

## REDUCE VELIE MODELS

MOLINE, ILL., July 5—New prices are announced on various models made by the Velie Motors Corp. The model 48 touring car is reduced from \$1,855 to \$1,595; the model 34 touring car from \$1,485 to \$1,385; the model 48 sedan from \$2,885 to \$2,485; the model 34 sedan from \$2,485 to \$2,085, and the model 34 roadster from \$1,485 to \$1,385.

## CLYDESDALE PRICES CUT

CLYDE, OHIO, July 7—Prices on Clydesdale trucks have been reduced on models from 1½-ton to 5-ton. Model 42, 1½-ton, is cut from \$2,750 to \$2,475; Model 65, 2½-ton, \$3,540 to \$3,250; Model 65E, 2½-ton, \$3,775 to \$3,450; 3½-ton, \$4,400 to \$4,100, and 5-ton, \$5,500 to \$4,500.

## CASE DOWN \$400 TO \$500

CHICAGO, July 9—Prices on Case Motor cars have been reduced from \$400 to \$500 on all models. The touring and sport models have been reduced from \$2,650 to \$2,250, the coupe from \$3,400 to \$2,900, and the sedan from \$3,750 to \$3,285.

## Goodyear Cotton Mills

## Resumes Manufacturing

DANIELSON, CONN., July 2—The Goodyear Cotton Mills, Inc., one of the leading industries of this section, engaged in the manufacture of tire fabric, will be reopened Tuesday morning on a one-shift working schedule of 40 hours per week, according to Vice-President P. W. Litchfield this week. The plant was closed 10 months ago and since has not turned a wheel.

On a one-shift 40 hours per week schedule, the plant will be on a basis of about 25 per cent of the production that was being turned out last summer.

## MEN OF THE INDUSTRY

E. A. Sattler, until recently director of sales of the Howe Rubber Corp., New Brunswick, N. J., and Theodore Weigle, formerly assistant sales manager of the same company, have taken over the sale of the entire output of the Eckrode Rubber Company, Inc., of Newark, of which Clement E. Eckrode is president. Sattler was elected vice-president of the company at a meeting of its board of directors several days ago. Sattler and Weigle are organizing for national distribution before the year's end.

Harry W. Walters has been named sales manager of the Herring Motor Co., Des Moines, to succeed N. W. Lovegrove, resigned. Mr. Walters has been with the Herring organization for nine or ten years, starting in a minor capacity, and for the past three years has been assistant sales manager. Walters has been elected to the place on the directory board of the Motor Trades Bureau of the Chamber of Commerce, made vacant by Lovegrove's resignation. Mr. Lovegrove has not announced his plans.

Charles B. Shanks, for more than six years manager of Motor World, has become associated with the Anderson Motor Co. of Rock Hill, South Carolina, manufacturers of the Anderson Six. He will appear on the official roster as vice-president of the corporation and will give principal attention to sales, advertising and service. Prior to Shanks' connection with the Class Journal Co. he was for ten years sales and advertising manager of the Winton Motor Car Co. of Cleveland.

George R. Morris has resigned as manager of the Chevrolet New York retail store to join W. C. Sills, former sales manager of Chevrolet, in the distribution of that car in the New England district. Harry Horton who has been manager of the Providence retail store will succeed Morris in the New York managementship.

Birger Jacobsson, formerly vice-president of the J. B. Crockett Co., New York, has resigned, and is now in the same kind of business with his own company, of which he is the president, with head offices at Stockholm, Sweden. His address is Birger Jacobsson Company, 11 Kardunsmakaregatan, Stockholm.

W. J. Drumpelmann, assistant sales manager of the Hudson and Essex for the last four years has resigned. He was formerly in the sales department of the Chalmers Motor Co. for three years. He has not announced his future plans.

H. M. Wirth, purchasing agent of the Kelsey Wheel Co., has severed his connection with that organization and is succeeded by Arthur Conklin who for two years was assistant to Wirth and for ten years with the company.

P. L. Emerson, assistant sales manager of Reo, has been transferred to San Francisco where he will take charge of the Reo branch.

## RECEIVER ASKED FOR FIRM

KANKAKEE, ILL., July 2—Dissolution and receivership of the Kankakee Automobile Co., and enforcement of directors' and stockholders' liabilities, were asked in the Kankakee, Ill., Circuit Court June 30. The company was alleged to have violated State laws and was never developed beyond the promotion stage.

# Calendar

## SHOWS

Sept. 5-10—Indianapolis, Automobile and Accessory Show in conjunction with Indiana State Fair, conducted by Indianapolis Automobile Trade Association, John B. Orman, Mgr.

Sept. 28-Oct. 8—New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January—Chicago, Automobile Salon, Hotel Drake.

Jan. 7-13—New York, National Automobile Show, Madison Square Garden, Auspices of N.A.C.C.

Jan. 28-Feb. 2—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.

## FOREIGN SHOWS

September—Buenos Aires, Argentina, Passenger Cars and Equipment, La Pabellon de las Rosas, Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery, Palermo Park, Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Sept. 23-Oct. 2—Berlin, German National Automobile Show, Auspices of German Automobile Mfg. Ass'n and German Automobile Club.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

## CONVENTIONS

Oct. 12-14, 1921—Chicago, Twenty-eighth Annual Convention National Implement & Vehicle Ass'n.

Nov. 22—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

## RACES

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

## Tommy Milton in Durant Wins Tacoma Sweepstakes

TACOMA, July 4—Before a crowd of 30,000 Tommy Milton in a Durant Special won the \$25,000 purse in the 250 mile event in the tenth annual racing meet here to-day. He finished the 125 laps in 2:34:15. Roscoe Sarles was second in a Duesenberg Special. The time was 2:34:52. Rene Thomas was third. His time was 2:38:47. Eddie Hearne in a Revere Special finished fourth; Tom Alley, Frontenac Special, fifth; Edward Miller, Duesenberg Special, sixth.

Eddie Pullen and Elliott, the former in a Duesenberg Special and the latter in a Leach Special were flagged from the course at the 100th lap. Elliott was off to a poor start. Soules led the field for the first fifty laps but was forced out in the sixty-first when he burned out pistons. Alley was forced to the pits in the fifty-eighth because of his left rear and again in the eighty-fifth.

Pullen drove a slow race because of pre-ignition troubles. Thomas changed to the rear in the eighty-fifth. Then Hearne followed suit in the eighty-eighth. Alley went to the pits again in the ninety-eighth because of his right rear.

The last twenty-five laps was a battle between Milton and Sarles, Milton passing the Duesenberg in the 105th. Elliott went to the pits in the 119th with left rear trouble. Milton averaged better than 98 miles and broke the record of 1920, adding 500 points to his year's record. Rickenbacker refereed with Harroun driving. A Marmon was pace-maker.

The weather was ideal for racing. Entertainment was provided by massed bands under the direction of the American Legion.

## Milwaukee Plants Hold "Model Factory Picnic"

MILWAUKEE, July 2—A "model factory picnic" was held Saturday, June 25, at Waukesha Beach, Pewaukee Lake, west of Milwaukee, by special co-operative arrangement among the biggest in-

dustries of Milwaukee for the edification of nearly 5000 social workers attending the national conference in Milwaukee, June 22 to 29. Each year the industries individually give outings for employees, usually at Waukesha Beach, the largest resort for this purpose in the vicinity.

A. Holmes of the Cutler-Hammer Mfg. Co. functioned as general chairman of the picnic committee. He was assisted by L. H. Fountain of A. O. Smith Corp., A. E. Borgeson of Avery Co., H. C. Best of National Brake & Electric Co., L. G. Meisenheimer of Globe Seamless Steel Tubes Co., E. H. Fitzgerald, Federal Rubber Co., and others.

## Commercial Haulers Want Parts Service Stations

MILWAUKEE, July 2—A resolution condemning the action of manufacturers of assembled trucks in opposing the establishment of parts service stations throughout the country by makers of unit parts was adopted by the National Association of Commercial Haulers at its annual convention which closed here to-day. The organization will do all it can to foster the service station idea.

Joseph X. Galvin, president of the National Team & Truck Owners' Association, addressed the members and told them he had come to the convention to urge amalgamation of the two associations. A resolution favoring such action was adopted but the actual working out of the details was left to the officers and executive committee.

F. J. Alvin, manager of the United States Motor Truck Co. of New York, which is headed by former Governor Alfred E. Smith, informed the convention that he had come to Milwaukee to pledge the assistance and support of his company to the association.

It was decided to separate the office of manager and secretary, both of which have been held by C. R. Collins of California. Collins will remain as manager while Tom Snyder of Indianapolis, who is secretary of the Indiana Transfermen's Association, will become secretary of the National Association.

One of the resolutions adopted favored passage of the Townsend highway bill.

## Sheet Metal Makers Form Group in M.A.M.A.

NEW YORK, July 6—The Sheet Metal Manufacturers' Association decided at a meeting in Detroit last week to dissolve and continue its work as a group of the Motor & Accessory Manufacturers' Association. It will be the first of many similar groups to be formed within the M. A. M. A. and the decision to dissolve will be followed by several other organizations of manufacturers engaged in the same line. The first group contains some of the leading sheet metal workers in the United States who do an automobile business.

The purpose of the various groups will be to discuss subjects of interest and value to the particular division or branch of the industry in which the members of the group are engaged; to advance and improve the entire industry as well as the particular branch represented; to collect and disseminate statistics and information of value to members; to promote such standardization of mechanical equipment, production methods and commercial practices as may be deemed desirable; to promote a spirit of friendly aid and co-operation within the groups and also with other groups in the industry. It is believed such co-ordination of effort by manufacturers with practically identical interests will largely increase the value of the M. A. M. A.

The affairs of the sheet metal group will be directed by an executive committee headed by H. P. Carrow.

## WILMINGTON ADDS EQUIPMENT

WILMINGTON, DEL., July 2—The directors of the department of Public Safety will soon place orders for about \$108,000 worth of motorized fire equipment. The department, which was recently created, expects to take over the bulk of the equipment of the volunteer fire department, in connection with the proposed new paid department, which will be under its care after Sept. 1. The local equipment to be bought is valued at about \$115,000, but it is not enough, hence the desire for additional equipment. The department is having the advice of former Chief Croker.

PUBLISHED WEEKLY AT 239 WEST 39th STREET  
NEW YORK, JULY 14, 1921

Thirty-five cents a copy  
Three dollars a year

### Making Blanks for "3450" Insulators

ONE of the first steps in the forming of "3450" Insulators for Champion Dependable Spark Plugs is the pugging operation. In this, a perfectly compact homogeneous cylinder is formed, which has mixed in it all the necessary materials

to insure strength and dependability.

The ability of "3450" Insulators to withstand shock, temperature changes, etc., is not a matter of guesswork, but is carefully worked out in advance by a corps of experienced engineers.

*Over half of all the manufacturers of passenger cars, trucks, tractors, marine and stationary engines, etc., use Champion Spark Plugs as regular factory equipment*

**Champion Spark Plug Company, Toledo, Ohio**

# WALTHAM SPEEDOMETERS AND AUTOMOBILE CLOCKS

## *Test these Waltham Master Instruments Yourself*

EVERY progressive automobile manufacturer is adding improvements to his car. This is why the only Air-Friction Speedometer in the world, invented by Nikola Tesla, perfected and developed by

Waltham during the past few years, has won the unqualified approval of the world's great automotive engineers. You will find this exclusive Air-Friction instrument upon such cars as the Cunningham, Lafayette, Leach-Biltwell, Lincoln, Packard, Pierce-Arrow, Renault, Rolls-Royce, Stevens-Duryea, Wills-Sainte Claire and others. It provides instantaneous accuracy with that dependability for which Waltham is famous. Go to any of the automobile agencies in your town whose cars are equipped with this distinctive Waltham instrument and ask for a demonstration of its performance. You will be shown a car upon which the Waltham Speedometer will register accurately and instantaneously every variation of speed and distance exhibited.

## Automotive Business Survives Adversity in North Dakota

Despite the elimination of farmer from new vehicle market and handicap of "no credit" attitude of the bankers, cars are running, dealers are keeping sales-rooms open and are well set for the certain revival.

By David Beecroft

**W**HETHER the Non-Partisan League, the general business depression, the high price of agricultural machinery and living in general, or the adamant policy of the banker, is directly responsible for the present mental attitude of the North Dakota farmer, the fact remains that he has been practically 100 per cent out of the automotive market since September, 1920, and will not be a buying factor during the remaining months of this year. In fact, it probably will be the spring of 1922 or mid-summer when the farmer is quite certain of 1922 crop figures that he is coming back into the purchasing field in anything like what may become his new standard of buying.

The North Dakota farmer is in anything but a favorable mental attitude toward buying, nor have the big branch houses of the agricultural machinery manufacturers been stocked from basement to roof as this year. Threshing machines and, in many cases, farm tractors fill loading platforms and stations, etc. The farmer is temporarily out of the machinery market. Sales are not 10 per cent of former averages in many sections. Tractor sales are best described as nil. The prospects of a fair crop over the entire State, and particularly in the western part, where there has not been a good crop since 1916, may result in a good sale of threshing machines and a few other necessities, but barring this the farmer is not buying

nor is he going to buy if he can help it. He is buying repair parts and doing his own repairing, but he is not purchasing new equipment.

Not only is the farmer sore at the continued high prices of agricultural machinery, but he is ill-tempered all along the line. Last August and September his Non-Partisan League friends urged him not to sell wheat when he might have realized \$2 or \$2.50 per bushel, and later he sold this wheat at \$1.40 or less, if he has sold. The value of everything he had to sell fell so that the index figure for farm products scarcely stood at 117, crops 109, livestock 109, while building material stood at 202, clothing at 181, house-furnishing goods at 262 and fuel and lighting at 194, and metal products at 138.

He cites that his products are not moving to the markets, and that index figures for the movement of his commodities stand far below par, namely, grain and grain products, 91, livestock 80. Farm products are at a low price. Eggs never sold cheaper in the State than they do at present. The North Dakota farmer is not complaining about the present low prices of farm products. He put his crop in at the lowest price basis possible this year. He is satisfied with the present price of wheat and is fully convinced that he can make good money out of his crop, but he is not satisfied with the price of farm machinery. Most of these farmers have no money with which to buy if

the prices were lower, but the almost complete stagnation of sales cannot be entirely laid to the shortage of money.

The tractor demonstration held during three days two weeks ago at Fargo, N. D., exemplified the North Dakota and western Minnesota farmers' state of mind. Twenty-six tractor makers exhibiting 46 tractors and eleven six- and eight-horse plowing outfits staged a 3-day plowing and seeding demonstration and covered the State with publicity, but the farmer stayed at home. On what should have been the biggest day, only 375 motor cars, outside of official cars, were counted at the busiest time of the day. They averaged three persons per car, a grand total of farmer attendance of 1125. Some farmers who were visited after the demonstration was over, said they would not wear out tires, or burn gasoline or buy railroad tickets to see a tractor demonstration this year. Some of them have not the money for railroad fares, or gasoline, and have to conserve their tires.

Yet North Dakota is sound financially. The best bankers in the State declare it is in better condition than many other States that profited by the war, and as a result shared in the inflation and over-expansion, and now must deflate. North Dakota was denied credits, largely due to the Non-Partisan League reputation and activities. In the sale of automotive apparatus very few of the big financing corporations continued to do business in the State, even the General Motors Acceptance Corporation withdrew from the State a year ago.

North Dakota lands have not increased in value. You can get the best land in the State, well improved, at \$40 and \$50 per acre, excepting in one or two sections very close to the larger cities. There is none of the \$500 inflated values of Iowa. In all lines of business, credit was denied during the war and you see no evidences of over-expansion or over-inflation. There is consequently no deflation problem ahead so far as industries in the State are concerned. Farmers in the western part of the State that did not have a good crop since 1916 have not had much chance at war profits. The eastern half of the State has had a good crop each year. The Red River valley occupying the east end, has never missed a crop, but has been subject to the same restrictions of credit that have affected the remainder of the State.

#### State of Mind Typical

The North Dakota farmer's state of mind can perhaps be considered as typical of the state of mind of farmers in many agricultural states, particularly those which depend largely on one crop, such as wheat, corn, cotton, tobacco, sugar, rice, etc. While the North Dakota farmer has not made the money that the farmers of other states have made, he has not the deflation and the North Dakota farmer is to-day perhaps a year ahead of the farmers in other states. As such, his state of mind is a good one to analyze and his State will serve as a mirror in which we may see conditions a year or 18 months hence as they may be in states that profited by war and inflation and are not yet through the deflation program.

The banker of North Dakota has made the farmer more or less what he is. The banker to-day, without reservation, refuses the farmer credit. He will give him no credit to buy a tractor. It makes no difference how many acres the farmer has or whether the land is free of mortgage or not. The banker has his one rule and one rule only, and that is not to lend. He will not handle farmers' notes for cars, or trucks, or tractors, or isolated houselighting plants, or any kind of agricultural machinery. He has only one line of advice to the farmer, viz.: "Get along with the old, repair it as necessary, but do not buy any new equipment."

Here is a typical example: A farmer in the eastern end of the State who has 320 acres of good land without mortgage and has owned it for 30 years and who, in addition, has \$32,000 of his savings loaned in mortgages, etc., wanted to buy a \$1900 car and asked his banker to carry his notes in payment of his car until fall. The banker refused. The car distributor took the notes and is carrying them in his own vault. The bank would not discount them.

This is the general attitude of the bankers of the State. The bankers in such cities as Fargo, 22,000; Grand Forks, 15,000; Devils Lake, 5000; Minot, 8000; Bismarck, 6000, and Jamestown, 5000, have funds, but will not lend them. The bankers in the smaller towns and villages have no funds and could not lend if the spirit were willing.

The bankers' attitude has not been improved by the fifty banks that have closed in the last few months, many of them just waiting until crops move and they can get some money from the farmers and re-open their doors. Some of them will not re-open.

#### He Could Sell

The bankers' attitude has engendered a reaction with farm implement dealers, agricultural machinery branch houses and automotive dealers. One of the biggest of the agricultural machinery manufacturers expressed it best:

"I could sell tractors and grain binders if I would take 3-year notes, but I refuse. I am not going to harvest this year's crop for the banker and that is what I would be doing if I sold a grain binder and accepted 3-year notes. The banker is going to take this year's crop. He took one-half of last year's crop and will, if he dares, take all of this year's crop. Let the banker handle the 3-year notes of the farmers for the tractor, or the grain binder, or the threshing machine. Let him harvest his own crop. This banker has a crop mortgage on a great many of the farms. He has had such crop mortgages for years, but he rarely had to execute them. He executed a few last fall, but has given notice he is going to execute many this fall. He is going to get his pound of flesh. This same banker must be careful he does not kill the goose that lays the golden eggs. Machinery is necessary to harvest crops as well as to seed them, and it is hoped the banker will see the error of his ways if he refuses too long to finance the farmer in harvesting a crop now when he has one worth harvesting."

This epitomizes the general situation in the State. This answers the question why tractors have not been sold this year in sections where many were sold previously, although agricultural conditions are best fitted for tractor use. This tells why tractors have not been used this year; due to shortage of money to buy fuel and the fact that the farmer has horses, that oats are cheap and the banker has told him to use what he has and not buy even kerosene.

From June 20 to July 20 is a period of coma in business cessation in North Dakota. This is the month of crop making or breaking. Business literally stops during this period. The farmer will not buy anything. The banker will not lend. The business man waits. By July 20 the prospect for a crop will be definitely known. The future is uncertain until about July 20. Hot winds before that date may burn the crop white in three days. More crops are ruined in North Dakota in July than any other time. When July 20 is passed and the banker knows what the crop is to be, he is a new man. He is in a position to make loans. He has a definite line on

the business for the next twelve months. The motor car dealer has a knowledge of what he can sell. The farmer has laid his plans. The biggest banker in North Dakota said last week he would discourage a farmer buying anything until the crop for this year is definitely known. He would handle no notes on tractors, trucks, cars, farm machinery or anything else going to the farmer. After July 20 he might make loans if crop prospects are good, and he will not make loans if crops are poor and the farmer has to be financed for another year.

But in spite of all this the North Dakota motor car dealer has carried on. Mortality in his ranks has been amazingly small. Very few sub-dealers have closed shops. The distributors are nearly all in business. The distributor in Fargo, Grand Forks, Devils Lake and Minot tells you his sales are all in the city, none in the country, and yet his country dealers have not gone out of business. They all have repair shops and garages. They sell gasoline, oil, tires and the necessary repairs and accessories. They have reduced overhead to the minimum. They repair tractors, isolated electric lighting plants, trucks, cars, in short, everything that has to be repaired, but they do not sell cars.

#### Salesrooms Open

Many of them have withdrawn their deposits with the distributors and technically may not be dealers in any particular make of car, but they still have their place of business and are operating. They are ready to go when business revives and the farmer comes back. L. C. Eby Buick distributor in Fargo, cites the case of a dealer in Lisbon, a town of 1800 population in the eastern end of the State, who has not yet taken a 1921 demonstrator, but he is still in business and is healthy and hopeful. Eby has 75 dealers, only 25 of whom have not withdrawn deposits. S. Welch, manager of the Dodge Minot agency, has 58 dealers and they all have garages and repair shops, although this year only two Dodge cars have been sold in the territory. The Overland distributor at Grand Forks, in the eastern end of the State, has 100 dealers, all of whom are in business, but few cars are being sold and sales for the district are scarcely one-twelfth that of a year ago. E. J. Siverson, Studebaker distributor in Grand Forks, with 45 dealers, reports them all in business, although practically all Studebaker sales are in Grand Forks. Mr. Hurst, manager of the Nash agency, with 14 dealers, has only three that have left up deposits, but they are all still in business. Dealers in Devils Lake tell the same story of no country sales and only city business. C. D. Haley, Studebaker dealer for 11 years, has only city sales, but a good country dealers' organization. There is not one of these country dealers that could not sell motor cars if farmer's notes could be handled. The spirit to buy is as strong as ever, but finances are weak.

Motor car dealers in cities, towns and villages of western North Dakota have learned how to live and carry on under the hardest severest school of training—necessity. They have been thoroughly tested and tried. They are happy. They have nothing to worry about. The prospects this year are good. They have learned how to do business without assistance of banks. These dealers are all set for the future. They have come through it all. They know how to convert part of their sales building into a garage and carry the overhead charges. They know how to handle two or three tire accounts and make dollars that way. Some of them have sold tractors for years and know why money can be made from farm machinery. They have practically gone on a cash basis for repairs and have learned how to say no when credit on parts or repairs is asked. They had to finance them-

selves and did not stock up on used cars. Had banks given them liberal credits they might find themselves stocked with used cars or with too big buildings on their hands or suffering in other ways from over-expansion. The credit to make such possible was denied and they are better dealers for it.

The strenuous character of the times is working a change for the better in many ways. Tire companies that attempted to maintain branches in some cities of 5000 population have closed them and put the tires on sale through dealers. This is becoming general. Some car dealers handle two or three lines of tires. There was not business to warrant a tire branch organization. Tire companies are giving discounts as high as 25 or 28 per cent and the car dealer sees prospects of making money on a tire account, particularly if he is a good merchant and turns his tire stock over six times a year, as he should. The tire companies will maintain warehouse stocks in different centers, but even the number of these can be kept low.

In western North Dakota you do not hear a dealer say he cannot handle different lines, such as cars, trucks, tires, tractors and isolated house lighting sets. He has learned how to do it and also to conduct a garage and repair shop besides. Necessity is ever the mother of invention and holds practically the same relationship to the automotive dealer. No dealer throughout North Dakota or Montana has much of a tire stock on hand. It never was lower. Dealers buy in small quantities. At present mail-order houses, such as Sears-Roebuck and Montgomery Ward & Co., are doing considerable tire business and their lines are cheaper than standard makes. The farmer knows this, but he is short of cash and is content to buy a cheaper article to tide him over until the crop comes in. Once the crop is in, leading tire concerns are looking for a big tire business in this area. There is not a car in the territory but is wearing out its old tires and running short on spares and tubes. Money may be short and there may be none for new cars, but all cars are in use. In one or two places you hear rumors of some cars jacked up in garages, but they are few. There are cases of where tires are worn out and there is no money to buy new ones and cars are laid on the shelf. The use of cord tires, even in Fords, has increased in towns and villages very much.

#### Old Tractor State

North Dakota is one of the best and oldest tractor states west of the Mississippi. The 77,000 farms in the State have an average acreage of 360 acres. Few farms are smaller than one-half section, 320 acres, and that is a good size for a two- or three-plow tractor. The land is generally level and the soil heavy. Summer plowing for wheat should be done in July and August, months when the temperature is too high and soil too hard for horses. This fact has sold many tractors.

Tractor sales this year have been virtually nil, whereas last year they were good. In Devil's Lake area, Mr. McCullough of Auto State Co., Ford dealer, has not sold a Fordson this year, but sold several last year, and if crops are good expects to make several sales this fall. C. D. Haley, Studebaker dealer, handling I. H. C. tractors, has sold one this year. In Minot scarcely a dozen tractors of all makes have been sold this year. The same is true of Grand Forks and Fargo. In parts of the State many tractors are not being used for lack of money to buy gasoline or kerosene. Most of the two- and three-plow tractors are in use, but one dealer found only one of twenty-four machines of his make in use in a part of his territory investigated. These machines were generally more than three-plow capacity. The farmer's

Two airplane views of the recent tractor demonstration near Fargo, N. D.

thought in not using the tractor is that he has his horses and they have to be fed. Hay and oats are cheap. He has no money to spend for fuel, oil or repairs.

In North Dakota the farmer bought a tractor to take care of the peak load on the farm, and last winter being unusually mild, he was able to do much more fall plowing with horses than formerly, and so the acute spring peak did not materialize. Still the farmer realizes the value of the tractor, and, as one said, that previous to buying his tractor he was not able to get all his fall plowing done, but the first year he had a tractor he fall plowed some of the land twice and the increased yield, or crop, the first year was worth one-half of what the tractor cost. Many of the farmers and most of the bankers have yet to be sold to the value of the tractor. Unfortunately, the banker fails to realize the economic value of the tractor. He fails to realize that its greatest value is making it possible for the farmer to plow when plowing does most good and to plow deeper and faster and thus increase his yield per acre. The banker to-day is dead against the tractor. He sees it only as a substitute too frequently for the horse. He urges the farmer to use the horse.

Repair business in North Dakota is good. Every car is being repaired and the farmers are doing more repair work than they ever did before. Sales of spare parts are normal and mostly on a cash basis. While in a Ford agency a farmer came in and wanted to buy a new car on time. The dealer would not sell him, but sold him parts for his old car. The frankness with which dealers refuse sales in which credit figures is encouraging. It is stimulating. It shows the good that comes out of depression and crop failures.

Garages generally are carrying reduced stocks of parts, and, as one man put it, "We carry only necessities." They have learned what accessories are needed and what ones are not. Brake linings, spark plugs, piston rings, springs, oils, greases, wrenches, tires, tubes, bulbs are typical of what are necessities. The accessory stocks are generally liquid. The shelves are not groaning under a load. Purchases from jobbers are in small lots. Sales are for cash, except where accounts have been carried for years and where payment is made in 30 days. There are repair shops that have been carrying farmers since last July, but they have gotten tired carrying such a load and, by refusing further credit, have found that the average farmer has some cash available.

Truck sales in North Dakota are largely in the four or

five cities, with a few in the country. Ford and Dodge jobs are finding their way to the farmers, and the Nash dealer in Grand Forks recently sold a truck to a potato farmer living nine miles out. Farmers are coming to realize that when they live ten or more miles from the railroad depot the truck becomes a real instrument.

George Dixon, Reo dealer in Grand Forks, looks for good truck prospects this fall, many of which will be farmers. W. A. MacMillan, manager of the Pence Co., Buick distributor in Fargo, has sold but six trucks since January 1, and not one in the last six weeks.

Most North Dakota roads are black gumbo and the main routes are well graded and dragged. In dry weather the surface is good, but the roads are impassable in wet times. The motor truck appeals to the North Dakota farmer, due to the short season he has for work. His situation is very different from that in Texas and Kansas, where the farmer has long seasons. In North Dakota the ground freezes in October and by that time he must have his fall plowing and threshing done and his grain delivered to market. He has an acute peak period, and the tractor and truck will be two essentials in his prosperity. He must not be allowed to buy too large a truck. From 1-ton to 1½- or 2-ton appear to be best suited. He may want more, but tear a page from the experience of the eastern farmer, who has found that a 1½-ton job is a better investment than a 3-ton job. The small pneumatic tire, not over five inches, has advantages in the country roads over trucks carrying seven- and eight-inch sizes, where the sides are worn out too quickly in ruts.

Sales of isolated house lighting plants have been slow for the past year, and practically none are moving now. Mr. Ashleman, Delco distributor for North Dakota, has recently disposed of his electrical equipment business, such as chandeliers, coffee percolators, bulbs, flat irons, etc. In fact, the Delco policy has been altered in this regard. For a time the sale to the farmer of this equipment was looked upon as a big part of the business, but difficulties developed. The regular electrical supply dealer of the town, who a few years ago did not have any realization of this new industry, has recently seen the possibilities of business and has resented the sale of equipment by the Delco or other dealer. Then, too, the distributor has had the problem of financing his dealers to a large extent in this equipment field. The dealer can now concentrate on sales of lighting plants and a few major equipments, such as pumps, washing machines, etc.

Service on these isolated lighting units has been a problem, and Willys light has reduced the free service period from one year to 90 days. After that the farmer pays at an hourly rate for service work. Some Willys light dealers are discontinuing the sale of miscellaneous equipment and concentrating on the lighting unit. Not all dealers are giving service. In some areas several Delco dealers do not give service and operate on a lower sales discount basis. Service in such areas centers on one large dealer, fitted to give service for the territory. The sale of lighting outfits through hardware stores is waning. Many garagemen and car dealers make good salesmen, and the garageman is especially well fitted to give service.

General conditions in four of the leading centers of North Dakota may be summarized as follows:

**Fargo,** in rich Red River Valley area. Car sales are 20 to 50 per cent of last year, Fords not included. Price reductions have greatly aided sales, which are nearly all in city and few in country. Western part of Fargo territory has had crop failures for two or three years. Over a dozen Fargo dealers, several of the curbstone type, have gone out of business in the last year. Fifty to 80 per cent of sales in Fargo are on time payment. J. D. Grant, accessory jobber, reports accessories selling well in eastern half of State and western Minnesota. He has five traveling men instead of seven. Payments are in 90 days; used to be 30 days. The eastern part of State is sound, but hard up. Over 80 per cent of farmers have motor cars.

**Grand Forks.** City business is good; no business in

the country. Farmers are doing their own repairing. Studebaker sales 85 per cent of last year. Ford sales slightly under last year, but parts sales are 100 per cent. Several new repair shops have started. No truck sales, and many large tractors were not used this year. Price reductions greatly stimulated sales. Dodge and Buick have few sub-dealers out of business. No distributors have quit business. Nearly 90 per cent of the farmers have motor cars.

**Devil's Lake.** Ford sales are practically equal to last year's. No truck sales; tractors slow. Farmers are doing most of their repairing. Studebaker sales in the city are good. Local banks are sound. General business in Devil's Lake is 50 per cent of normal. Farmers are starting to buy trucks. Several dealers sell tractors, along with cars, tires, etc. Farmers in this community are wealthy and own their land. Nearly 100 per cent of farmers have motor cars.

**Minot.** Crop conditions within a radius of 10 miles are poor. Crop burned last week. Thirty-eight banks failed in this territory, which has not had a good crop for five years. Sales are in cities only. Few tractor or farm implement sales are reported. No truck sales. More car sales, after price reductions, than for eight months previously. Repair business was good until July 1, when it became slack. Few sub-dealers are out of business. Firms that sold 20 trucks last year have sold but one this year. Ford sales are ahead of last year, but sales are only in cities and towns. No cars are laid up. Repair business and tire sales are largely cash. Dealers sell tires, accessories, tractors, etc.

## Performance of the Liberty Engine

**E**XTENSIVE tests of the Liberty twelve-cylinder aircraft engine under varied conditions have recently been made in the altitude chamber of the Bureau of Standards at Washington, and the results obtained published in Report No. 102 of the National Advisory Committee for Aeronautics. The object of the test was to determine the performance of the Liberty engine under such conditions as would yield sufficient information to determine its value for aviation use. A number of the performance charts are reproduced herewith. All the conditions of the tests are indicated on the charts. It may be pointed out, however, that the residual heat is the difference between the heat value of the fuel consumed on the one hand and of the heat equivalent of the horsepower output, the exhaust heat and the jacket heat on the other. This factor therefore includes the heat value of the unburnt fuel. As the fuel requires 15.3 lb. of air per

pound of fuel for its complete combustion and the leanest mixture contained only about 14 lb. of air per pound of fuel, it is clear that some of the fuel must always pass through the engine unburned or only partially burned.

The greatest value of such data as furnished by this test can be realized only by its comparison with similar results obtained with other engines. This not only permits of the engines being judged as to their relative value for a given class of work, but also indicates reasons for superiority in performance of one type over another.

There are two outstanding conclusions, however, to be drawn from the test itself—namely (1) that the carburetor control is inadequate above 15,000 feet and (2) that the most promising line of development for improved altitude performance lies in increased mechanical efficiency through decreased friction horsepower, and in such changes as will prevent the decrease in volumetric efficiency.

Charts showing performance, heat loss, etc., of Liberty aircraft engine under various conditions

# One Four and One Six-Cylinder Chassis Comprise Benz Line

Aside from engine, chassis are practically identical, and possess but few novel features. Transmission brake has provision for water cooling. Steering gear has unhardened screw with non-adjustable babbitt-lined nut. Torque tube and radius rods preferred to Hotchkiss drive.

By Benno R. Dierfeld

**A**T the present time the Benz company is manufacturing two chassis models, a four and a six, of 45 and 70 hp. engine rating, respectively. It is natural that a design with 36 years of experience in the automobile business behind it does not need to be changed very often, hence an annual model is not a feature of the Benz program. The two models here considered are practically identical except as regards the number of cylinders and the rear spring suspension, which latter is of the cantilever type in the six and the half elliptic type in the four-cylinder model.

The engine drives through a cone clutch to the four-speed transmission, which forms a separate unit. The propeller shaft has a single universal joint, and the rear axle is provided with radius rods. The rear axle drive is by bevel gears. Steering gear and control levers are arranged on the right-hand side. One brake acts on the transmission, the other on the two rear wheels. The frame is in-swept at the front and has a kick up at the rear. The fuel is pressure-fed from the rear tank.

The L-head cylinders are cast in pairs as will be seen from Fig. 1. The valves have aluminum cover plates and the camshaft is driven by an easily adjustable chain which also drives the high tension magneto. The starting motor and generator are mounted on cast brackets on the crankcase arm. The water pump is driven by the same shaft as the magneto. Carbureter air is pre-heated in a sleeve surrounding the exhaust pipe; furthermore, the inlet manifold is heated by water from the jacket header. The aluminum crankcase is divided horizontally and has in its upper part three babbitt bearings for the crankshaft, which are offset 15 mm. from the axial plane of the cylinders. See Fig. 3. The pistons are of cast iron and the big ends of the connecting rods have babbitted bearings. Between the two cylinders of each pair a cast passage is provided, connecting the inlet manifold with the inlet valve chamber on the opposite side of the engine,

thus insuring good preheating of the fresh mixture. See Fig. 2. The two inlet valves of each cylinder pair are located between the two exhaust pipes. To prevent rattle the ends of all valve tappets are provided with inserts of vulcanized fiber.

The carbureter is of the Benz-Zenith type. On the four cylinder models fuel feed is by exhaust gas pressure and when the engine is at rest the necessary tank pressure can be produced by a hand air pump on the steering post. In order to maintain a constant pressure on the fuel tank a pressure regulating valve, a sectional drawing of which is shown in Fig. 4, is used. The device consists of two valves, A and B, located one above the other in a common valve housing. The exhaust gases enter through strainer J and valve A, whose spring F has but little tension. By adjusting the tension of valve spring G the pressure in the fuel tank can be regulated. On the six-cylinder model a small engine-driven air pump furnishes compressed air for fuel feed and no exhaust pressure device is required.

Fig. 2—Longitudinal section of Benz 4-cylinder engine. Note inlet passage cast between cylinders of each pair

Fig. 1—Exhaust side of Benz 6-cylinder engine. Note location of water pump, peculiar shape of fan and fan adjustments

Ignition is by high tension magneto and battery with one set of spark plugs.

The tubular radiator is connected flexibly by a ball-shaped trunnion to one side of the frame, in order to avoid stressing the radiator core. The pump is of the centrifugal type and the fan is belt-driven from the crankshaft. The fan shaft runs on ball bearings and is supported on a stud carried on the short arm of a double armed lever. The fulcrum of the latter is supported by a cast bracket. Secured to the long arm of the lever is a coiled spring with a butterfly nut, seen in Fig. 1, by which the tension of the fan belt can be easily adjusted. A grease cup provides lubrication for the fan shaft bearing.

Engine lubrication is effected in the following manner: From the sump A, Fig. 5, the oil flows through a strainer to the oil pump B, which forces the oil through pipe C to the main oil tube D. The latter runs parallel with the crankshaft inside the upper crankcase half.

Fig. 3—Transverse section of engine. The crankshaft is offset

Fig. 9—View showing clutch and brake controls, method of mounting gearbox, etc.

Three branches lead to the crankshaft bearings, the branch H to the magneto shaft and the branch E to the oil pressure gage on the dash. Oil working its way through the crankshaft bearings flows along the shaft webs to the oil pocket J, whence it is forced to the big end bearings by centrifugal force and lubricates the pistons and cylinder walls in the form of a spray. On both sides of the camshaft there is an oil pocket O which collects a part of this oil spray. Oil thus collected is led through suitable passages to the camshaft bearing surfaces. The piston pin bushing is connected by a drilled passage with the interior of the hollow piston pin and the oil necessary for its lubrication is wiped off the cylinder walls. The excess oil, running down the crankcase walls, flows back through the large strainer K to the sump A. The chains used for the camshaft and magneto drive are lubricated by an oil jet coming from a fine hole G in the tube D.

In order to regulate the quantity of oil pumped to the main oil tube, oil pressure valve P is provided on the crankcase arm. It is connected by tube R with the main oil tube D and is shown in detail in Fig. 6. Valve V is held to its seat by the spring F, the tension of which can be regulated by the set screw S secured with a lock nut. As soon as pressure in the main distributing line exceeds a certain set valve the valve V opens and the superfluous oil flows back through passage Q to the crankcase. In order to prevent unauthorized adjustment of the oil pressure valve, it is provided at the factory with a cap which is secured by a lead seal. The height of the oil level in the crankcase is regulated by means of the three-way cock L, Fig. 5. The oil filler tube also serves as a breather. M is the drain plug, which is connected with a cylindrical strainer.

Fig. 7 shows two sectional views through the pump. The pump shaft N is driven by the intermediary shaft M and the bevel gears from the camshaft and bears on its lower end the slotted member K, forming a guide for blade B of the vane-type oil pump. The pump chamber is closed by cover L, upon the removal of which the pump with drive can be removed.

The clutch cone is of pressed steel in the 45 hp. model and has a leather lining. It is pressed into the flywheel by the clutch spring D. Declutching is effected through the pedal, lever H, Fig. 8, and two shackles G. The spring sleeve C is lubricated through the oil screw F. The clutch shaft is connected with the transmission main shaft by the intermediary shaft M and the enclosed universal joint N. A simple clutch brake, shown in Fig.

Fig. 4—Fuel feed pressure valve, operated by exhaust.

Fig. 12—Horizontal section through rear axle, propeller shaft, torque tube and radius rod. Brake equalizer is shown in upper left corner

Fig. 14—Longitudinal section through steering gear

9, is provided. It consists of two leather-lined brake shoes S, pressed by a spring against flange R of the clutch cone, this brake can be adjusted by loosening the lock nut T and turning the adjacent nut. In the 70-hp. model the clutch cone is made of cast aluminum.

The gearbox, shown in section in Fig. 10, has four forward speeds. All transmission shafts run in ball bearings. When the reversed gear is engaged the gear shift rod M is secured in its position by a locking device. By moving the gear shift rod H to the left side, the nose D of a two-armed lever is pressed down, the other end E of which then is moved upward, thus entering between the two projections S of the shift rod M and locking it. The shifter rods are locked by the two set pins, F and G. The bearings of the transmission shafts are made dust and oil tight by spring disks of bronze, Q, which are pressed by screw rings against the outer and inner race of the corresponding ball bearing.

The design of the cross pin universal joint is clearly shown in Fig. 10. The rear part of the case has two diametrically opposite screw plugs for lubrication and a pulley for the speedometer drive. This form of speedometer drive is preferred to the front wheel drive, because it is protected against mud and no provision needs to be made to compensate for the spring action.

Oil leakage from the universal joint cases is prevented by a ball sector-shaped piece pressed by a spring against the spherical interior surface of the case and a felt ring held by a screwed retainer.

The transmission brake drum is bolted together with the forward part of the universal joint case. The brake shoes of steel have cast iron linings and their right ends are swiveled to a bracket bolted to the transverse frame member. See Fig. 11. The other ends are operated by a lever and bolt. When the linings become worn slightly the shoes can be adjusted by a butterfly nut. After more extensive wear the brake rod is shortened by screwing up the yoke. In case of unequal distance of the brake shoes from the drum, the lock nuts of the two screw J, K are loosened and the screw adjusted accordingly. To prevent undue heating of the transmission

brake, a water tank is provided at the right side of the transmission case from which cooling water is forced by exhaust gas pressure to the sight feed with stop cock at the dashboard, whence it is allowed to flow to the brake drum. The brake shoes also have cooling ribs on the outside.

A horizontal section through the drive shaft and rear axle is shown in Fig. 12. Two parallel radius rods serve to transmit the propulsive effort from the rear axle to the frame. They have an eye at the rear end supported by an axially drilled pin with provision for grease lubrication. The front end has a ball joint spring-cushioned to damp out road and starting shocks. This joint is lubricated with grease through a drilled pin. The rear wheels can be detached after removing the axle cap and axle nut by inserting a wheel puller in place of the cap.

The design of the rear wheel brakes is clearly shown in Fig. 13. Inside the brake drum are the two brake shoes lined with asbestos fabric and carried on two pivots. The free ends are connected by toggles and a link with a lever arm. Equalization of the two rear brakes is effected by means of the simple ball-headed balance lever arrangement, shown in Fig. 12. When the brake shoes are worn adjustment can be made in the brake linkage, but it can also be made on the brake itself, after removing the rear wheel, by loosening the check nuts and lengthening the toggles.

A longitudinal section through the steering gear is shown in Fig. 14. By means of the steering wheel, motion is given to the long unhardened steel screw and the babbitted non-adjustable nut. This screw and nut arrangement is said to have proven entirely satisfactory. The throttle and spark levers are arranged in the usual manner.

The front axle, Fig. 15, has forked ends and the steering knuckle pivot has plain bronze bushings with ball thrust bearings. The front wheel hub has ball bearings and is closed on the inside by felt rings and metal washers.

In the following table are given some particulars and dimensions of the two Benz cars:

## A New Fabric Universal Joint

IN the past some trouble has been experienced with fabric type universal joints from the bolts loosening and the fabric around the bolt holes being torn or worn out in consequence. In the M. & E. Griptite, a new design, it is sought to overcome this difficulty by embedding six tubular steel spreaders in the disks, one at each bolt hole, these spreaders bulging the fabric into semi-circular ridges exactly fitting the formed clamping washers. The spreaders are in contact with the bolts and impart to them part of the torque from the disks. They are also claimed to increase the density of the rubber immediately under the clamping washers, thus allowing greater initial clamping pressure on the disks and reducing the need for retightening to a minimum.

The M. &amp; E. Griptite universal joint

## A Demountable Body Carriage

THE demountable body carriage outfit for truck use, shown in the accompanying cut, consists of one sub-frame, two carriages and two sets of wedge-blocks. Separate units can be added as they are needed. The parts are of steel construction throughout. Channel irons which serve as rails for the steel wheels under the car-

riage to roll on are sunk level with the floor and do not prevent the use of hand trucks on the shipping platform.

The sub-frame is of steel construction, with a channel steel track, the whole being fitted to the chassis by brackets bolted through the sides of the frame. It is made to fit any length and width of chassis. There are four locks, two on each side, which keep the carriage and body in place on the chassis. It is said to have been proven in service that the bodies cannot come off accidentally. The carriage, which can be mounted under old as well as new bodies, is of a construction similar to the sub-frame. It has steel wheels fitted with roller bearings, which make the body easy to roll when unlocked. It is said that two men can easily push a body loaded with 2½ tons, and five men 7 tons. The leveling device consists of the wedge-blocks mounted on the platform front and the V-blocks on the rear of the chassis. Backing the truck into the wedge-blocks always brings the body to the same level, no matter whether empty or loaded and locks it there until the body is shifted. The roll-off carriage and accessories necessary for use with it are manufactured by the Perin Automotive Engineering Co.

demountable bodies

# Experiments With Localized Charge and Supercharging Engines

Report of investigations demonstrating how mean effective pressure and economy can both be increased by use of stratified charge. Excess air and cooled exhaust gas are employed as diluents to limit maximum temperature of cycle and prevent detonation. Unusually high fuel economy at part load is obtained by use of non-throttling engine.

By Harry R. Ricardo\*

IF we consider the usual four-stroke cycle, we find that there are only two obvious ways of increasing the power output, namely, by increasing the mean pressure, or by increasing the piston speed. The former does not leave much ground for hope, for the volumetric efficiency is already within 1 or 2 per cent of the highest obtainable, and the compression ratio has already been carried to the highest safe limit consistent with the fuels available. Moreover, a little investigation will show that any further increase in compression must result in a very large increase in the maximum pressure, involving the necessity for heavier moving parts; hence such increase of efficiency as might be obtained by increased compression will be largely counterbalanced by enhanced mechanical losses due to the heavier masses.

So far as piston speed is concerned, there does not appear to be very much hope either. Until recently the piston speed was controlled primarily by the inertia of the reciprocating masses, but since the advent of the aluminum piston the controlling factor has been shifted to the valve gear and the provision of adequate valve area. By careful design, the limit can no doubt be still further raised, but only at the expense of greatly increased cost of manufacture. Again, if either the mean pressure or the piston speed could be increased, another controlling factor would play havoc, namely, the difficulty of dealing with the intense heat flow, which is already a serious problem, even in the smallest engines. This difficulty can be alleviated to some extent by the use of aluminum piston and cylinder head and water cooled exhaust valves, but it cannot be altogether avoided by such means, and when staved off in one direction it soon crops up in another. In whatever way the problem may be viewed, the conclusion is invariably reached that in order to obtain any really substantial gain in power or economy, the question of heat flow must first be attacked, and some means or other must be found to reduce the flame temperature. In this direction lies not only the one hopeful solution of increasing the power, but also the one chance of a really substantial gain in economy, since the two principal losses, namely, the loss due to direct transfer of heat to the cylinder walls, and the even larger loss due to the increase in the

apparent specific heat of the working fluid at high temperatures, are both directly dependent upon the maximum flame temperature.

If we consider the working fluid from the point of view of an air to gasoline mixture, we find that the proportion giving complete combustion has a heat value in round numbers of 100 B.t.u. per cu. ft. With this mixture density, the combustion of the fuel will raise the temperature of the working fluid to approximately 2500 deg. C. (4532 deg. Fahr.), taking into account the increase in the apparent specific heat and dissociation. At this high temperature the loss of heat, and still more the loss due to the increase of specific heat at high temperatures, are extremely serious.

The air standard efficiency of the cycle is independent of the maximum temperature, so long as the gases are expanded to the same volume as they occupied before compression, but this holds good only when there is no loss of heat, dissociation, or change in the specific heat of the working fluid. When, however, these considerations are taken into account, it will be found that the ideal efficiency falls

Fig. 1.—Relation between air cycle and ideal efficiencies and heat added per cu. ft. of mixture. Compression ratio 5:1

rapidly as the temperature rises.

In Fig. 1, one curve shows the theoretical efficiency obtainable with a compression ratio of 5:1 on the assumption of no heat loss, no dissociation and constant specific heat; this curve is a straight line, and is independent of the flame temperature or heat value of the mixture. The other curve takes into account the loss due to change of specific heat, and also allows a minimum figure for the jacket loss, and it will be observed that as the heat value of the mixture, and therefore the flame temperature, is reduced, the efficiency rises until, at the point of no heat supply, it would become equal to the air cycle efficiency.

Consideration of this curve shows at once the desirability of working with a weak mixture, and therefore a lower flame temperature, but unfortunately gasoline vapor has only a very narrow range of burning, and so long as the mixture is homogeneous it is not possible under ordinary conditions to employ a mixture weaker than about 85-90 B.t.u. per cu. ft. At this strength the maximum flame temperature is but little lower, since the first effect of reducing mixture strength with gasoline is to reduce the proportion of dissociation and so affect the temperature but little. Any attempt to work below this density

## IDEAL INDICATOR CARDS FOR VARIOUS CONDITIONS

Fig. 2—20 B.t.u. per cu. ft. Fig. 3—90 B.t.u. per cu. ft. Fig. 4—66 B.t.u. per cu. ft. Fig. 5—66 B.t.u. per cu. ft. plus 33 per cent supercharge. Fig. 5A shows Figs. 4 and 5 superimposed. Fig. 13—Light spring diagram, showing admission of supercharge

with a homogeneous charge results in incomplete combustion, and ultimately so slow a rate of burning that flame lingers in the cylinder and ignites the fresh charge on entry, causing the familiar popping back through the carbureter.

It is evident that were it found possible to work with a much weaker average mixture density, and so obtain a very substantial improvement in thermal efficiency, the mean pressure would be reduced, though not in direct proportion to the heat value of the mixture, because the higher efficiency obtained would mean that a greater proportion of the available heat would be converted into power.

To appreciate the effect of working with a low mean mixture strength it is interesting to consider what would happen if into a cylinder containing nothing but pure air, a paper bag containing a small proportion of fuel and air of normal mixture strength were inserted, and that by some means the contents of this bag were ignited at the end of the compression stroke. The bag would immediately burst, and the burning mixture would be projected into the large excess of air present in the cylinder, thereby heating the air and raising its pressure. The average temperature of the air under these conditions would of course be much lower than if it were saturated with fuel; on the other hand, if the same quantity of fuel had been allowed to mix with the whole of the air it would not have ignited at all.

Fig. 2 shows the sort of indicator diagram which would be obtained supposing that the contents of the paper bag represented 20 per cent of the total cylinder volume, the remaining 80 per cent being either pure air or air and exhaust gas. It will be observed that the maximum flame temperature would in this case be only about 1100 deg. C. (2012 deg. Fahr.). With such a maximum temperature the loss of heat to the walls and the loss due to change of specific heat would be very small, and the efficiency

would be very high in consequence. The theoretical efficiency would under such conditions be just under 45 per cent for a compression ratio of 5:1.

In the experiments described later in this paper the author aimed at—

1. Reducing the mean mixture strength by stratifying the charge and so obtaining a high thermal efficiency.

2. Reducing the heat flow by lowering the flame temperature.

3. Recovering and even increasing the mean pressure by the addition of extra air in the form of a supercharge.

In Figs. 3, 4 and 5 are shown three indicator diagrams which illustrate the objects in view. Fig. 3 shows a normal diagram for the most economical mixture strength with a homogeneous charge, namely, about 90 B.t.u. per cu. ft. This diagram shows a maximum temperature of about 2500 deg. C., a limiting efficiency of 32 per cent, and a mean effective pressure of 138 lb. per sq. in. indicated.

Fig. 4 shows a diagram for a mean average mixture strength of 66 B.t.u. per cu. ft. In this case the maximum temperature will be about 1880 deg. C., the efficiency 34.5 per cent, and the mean effective pressure 98.5 lb. per sq. in.

Fig. 5 shows a diagram also for a mean average mixture strength of 66 B.t.u. per cu. ft., in which the weight of air has been increased 33 per cent by means of supercharging. The effect of the supercharge will be to enlarge the whole diagram by 33 per cent without affecting the temperature and, therefore, the efficiency, but increasing the mean pressure to 152 lb. per sq. in. Under these conditions, not only will the high efficiency theoretically obtainable under the conditions of Fig. 4, be maintained, but the mean pressure will be restored and even raised to well above that obtainable under normal conditions of working.

The experiments may be divided into three phases.

1. An investigation into the efficiency obtainable by varying the mixture strength under normal conditions.

2. An investigation into the possibilities of reducing

the mean mixture strength by working with a stratified charge.

3. Experiments combining the use of a stratified charge with supercharging.

For the first series of tests a highly efficient single-cylinder vertical engine, direct-coupled to a swinging-field dynamometer, was used. The engine was provided with a Hopkinson optical indicator and a carbureter in which the whole of the fuel was thoroughly vaporized, and in which the control of the fuel supply could be regulated with extreme nicety by means of a very fine needle valve. The accuracy of the apparatus was such that the power could be read with certainty to within  $\pm 0.3$  per cent, and the fuel consumption to within  $\pm 0.5$  per cent. Very careful determinations were also made of the mechanical and pumping losses, so that the indicated power could be arrived at from the brake horsepower, and also checked by indicator diagrams which were taken at frequent intervals.

A summary of the results of these tests is shown in Fig. 6 which explains itself. It will be observed that so soon as the mixture strength is reduced to any substantial extent beyond that at which there is just sufficient air to combine completely with the whole of the fuel, incomplete combustion counteracts any gain in efficiency due to the reduced flame temperature. Unfortunately, however, the absolute mixture strength could not be definitely determined because no means were available of measuring accurately the air supply; consequently the curves showing the actual performance may be as much as  $\pm 2$  per cent out in a horizontal direction.

The second series of tests, which was carried out during 1913-1914, was undertaken with a view to determining:

1. Whether it was possible by means of stratification to work with a low mean mixture density.

2. Whether, if it were possible to do so, the results obtained would be found to be in agreement with those theoretically possible, or whether any disturbing factor would crop up to prevent their attainment.

To carry out this series of tests an old single-cylinder vertical engine of 5 in. bore and 6 in. stroke was resurrected and provided with a new cylinder, cylinder head and valve gear. In view of the fact that the use of a stratified charge and a low mean mixture density would, if successful, result in a very low flame temperature, no water jacketing or other means of cooling was provided for the cylinder or cylinder head. The cylinder head was so formed, and the position and timing of the valves were so arranged, that a rich mixture of fuel and air and a large additional supply of pure air entered the combustion chamber at different points, and were so directed that even after their entry, and in spite of very vigorous turbulence, they would not completely mix, the rich fuel mixture remaining always in the neighborhood of the sparking plug, while the air

Fig. 6—Relation between m.e.p. and fuel consumption, homogeneous charge.

remained over the piston.

The power output of the engine was controlled entirely by the quantity of fuel admitted during the suction stroke, no throttle valve or other means of control being provided, so that at all times and under all conditions a full air charge was taken into the cylinder.\*

The results proved that the degree of stratification actually obtainable was far greater than expected. It was found possible to reduce the mean mixture strength from a useful minimum of 85 B.t.u. per cu. ft. under ordinary conditions of working, down to as low as 10 B.t.u., and yet obtain perfectly regular running.

A Hopkinson optical indicator was fitted in the combustion head, and the indicator diagram thrown on to a glass screen covered with tracing paper was carefully watched; a number of indicator diagrams were photographed, but for the most part the diagrams were traced in pencil, which was very much quicker; at the same time the brake horsepower of the engine was recorded.

These experiments proved more successful than had been hoped for, and were in very fair agreement with the theoretical figures. The following observations are taken from notes and test reports of 1913-1914:

1. The engine could be started at all times, even on the coldest day in midwinter, on the first pull-over.

2. When running light with an indicated mean pressure of about 14 lb. per sq. in., the exhaust, though perfectly free, was almost inaudible. Also the cylinder barrel remained quite cool, and it was possible to bear the hand on any part of the cylinder head or exhaust pipe even after an hour's running on no load.

\*A diagrammatic view showing the principle of operation of the Ricardo localized charge (constant compression) engine was shown on page 1243 of AUTOMOTIVE INDUSTRIES for June 16, 1921.

Fig. 8—Relation between fuel consumption and indicated mean pressure in engine using stratified charge

Fig. 9—Relation between thermal efficiency and mixture strength. Observed results are those obtained with engine using stratified charge

3. So long as the admission of fuel was not altered the speed of the engine remained absolutely uniform and the indicator diagrams extraordinarily consistent. Fig. 7 shows an exposure of 20 seconds, taken with the engine running light at about 600 rev. per min., and therefore represents about 100 complete cycles.

4. By opening the needle valve and increasing the admission of fuel the engine would immediately accelerate even from the slowest speed of 120 rev. per min.

5. One very noticeable feature was the extraordinary rapidity of ignition, due to the violent turbulence set up. A fixed ignition timing of 3 deg. before dead center sufficed for all speeds and loads, and invariably gave a perfectly vertical line of pressure rise on the diagrams.

6. Some hundreds of readings of fuel consumption were taken at all loads ranging from dead light to full load, and the mean results of these are shown in Fig. 8, which gives the fuel consumption obtained with indicated mean pressures ranging from 14 to 120 lb. per sq. in. Fig. 9 shows the indicated thermal efficiency actually obtained, plotted against that theoretically obtainable, and presents, on the whole, very tolerable agreement. On the light loads there is undoubtedly some loss due to incomplete combustion.

7. On full load the running of the engine was in every respect normal, but, of course, the absence of any water jacketing prevented the maintenance of full load for more than a few seconds at a time.

8. Perhaps the most noticeable feature of all was the general sweetness and smoothness of running and the extraordinary responsiveness of the engine. Unfortunately, owing to the poor mechanical design of the engine generally, it was not possible to run it at high speeds, the extreme safe limit being only about 800 rev. per min. Tests were made over a speed range of from 150 to 800 rev. per min., and these showed practically no difference in the indicated fuel consumption, the shape or regularity of the indicator diagrams or the general running.

Subsequent experiments carried out on other engines proved, however, that the results obtained on the special experimental model could not be always repeated. Further bitter experience has proved that the author was quite unusually fortunate in selecting proportions in the first instance, and that much further experimental work is required before the system of controlling on the fuel alone can be so boiled down as to be rendered applicable to any type of engine. Quite recently another and much larger engine has been built, operating on the same principle, and employing as far as possible the same form and proportions of combustion chamber. This engine, which has been running at the author's laboratory for the past twelve months, has proved equally efficient, but all attempts to adapt the principle of operating by stratification alone over the whole range of load to existing engines have ended in more or less disappointment.

#### Experiments With Supercharging Engine

Having established that, under certain conditions at all events, a very substantial degree of stratification could be maintained with, at the same time, sufficient turbulence to insure rapid combustion (although the two conditions may not at first sight appear compatible), and having also proved satisfactorily that under these conditions a very marked reduction in the maximum temperature and a corresponding gain in the efficiency could be obtained, the third series of tests was commenced.

For the purposes of these tests, a special experimental engine was designed using a system of supercharging generally similar to that devised by Sir Dugald Clerk and completed in 1915. This engine, a section of which is shown in Fig. 12, had a bore and stroke of 110 mm. and 140 mm. respectively, and was designed to run at a normal speed

of 1500 rev. per min. The upper portion of the cylinder was quite normal and of the L-head type, with the inlet valve placed vertically over the exhaust valve, and operated by a push rod and overhead tappet. The piston, however, was formed in two parts, a plain head of aluminum carrying the piston rings, provided with a very short skirt furnished with a number of small oil grooves and a circular crosshead of considerably smaller diameter, the piston and crosshead being connected together by a hollow aluminum trunk. The crosshead portion of the piston, which carried the wrist pin, reciprocated in a white-metal-lined guide, which was carried in a separate casting interposed between the cylinder and the crankcase.

In its original form the crosshead was of mild steel, and the piston and trunk were of aluminum, the two members being screwed together as shown in Fig. 12. This form of construction, though it cannot be considered mechanically sound, proved very convenient for experimental purposes, since the upper half of the piston could be changed quickly and easily, in order to vary either the compression or the contour of the head, which latter proved to be very important. In point of fact it has never given any trouble in the experimental unit, where great care was taken in the machining of the threads, but the author would never advocate such a construction other than for experimental work. The piston and crosshead, as a whole, were fairly light, the total weight with rings and pin being only 39 oz., which compares quite favorably with that of an aluminum trunk piston of the same size, though aluminum pistons were scarcely known at the time of the experiments.

The cylinder, which was very short, was recessed into the separate casting carrying the crosshead guide, and the extension of the cylinder skirt was provided with a ring of ports uncovered by the piston at the bottom of its stroke; these were surrounded by a movable sleeve or shutter, so that they could be closed off at will. Surrounding the crosshead guide was an annular chamber having a minimum capacity of about 60 cu. in., but the capacity could be varied at will over a wide range by means of hollow detachable plugs. A series of very light phosphor bronze automatic valves admitted air to the chamber and acted as non-return valves during the compression stroke.

Lubrication of the cylinder walls was provided for in the following manner: When the piston had almost reached the top of its stroke a series of small holes drilled through the wall of the crosshead were uncovered above the top of the guide. Owing to the reduced pressure in the crosshead chamber at this point as compared with the pressure in the crankcase, a small quantity of oil-laden air passed out through these holes, with the result that the oil was deposited on the walls of the cylinder, where it was picked up by the short skirt of the piston and distributed evenly over the inner surface.

#### Operation of Supercharging Engine

In its original form the cycle of operations was as follows:

Commencing at the beginning of the suction stroke, the piston, as it descended, drew from the carbureter a charge of gasoline vapor, and air of normal proportions. Toward the end of the stroke the ports round the lower end of the cylinder were uncovered and a charge of air compressed in the crosshead chamber to a pressure of about 12 lb. per sq. in., entered the cylinder. Almost simultaneously with the opening of the ports the main inlet valve was closed. The supplementary air from the crosshead chamber raised the pressure of the cylinder contents to about 5 lb. per sq. in. above atmospheric pressure, and at the same time formed a layer of air above the piston, which remained in a more or less stratified condition throughout the com-

pression stroke. Fig. 13 represents an ideal indicator diagram, showing the cycle in the cylinder during the suction stroke and the admission of the supercharge air, and Fig. 14 shows an actual indicator diagram taken from this engine. During the upward stroke the contents of the cylinder were compressed, the combustible mixture remaining more or less at the top, and the pure air forming a layer over the piston. Meanwhile, another charge of air was drawn into the crosshead chamber.

At the end of the suction stroke the contents of the cylinder consisted of about 70 per cent of combustible mixture of normal strength, namely, about 95 B.t.u. per cu. ft., and about 30 per cent of air, the former being concentrated more or less in the valve pocket, and in the neighborhood of the sparking plug, and the latter forming a layer over the piston. The mean mixture density of the whole of the cylinder content was therefore only about 66 B.t.u. per cu. ft., a density which, under ordinary circumstances, would not have been inflammable. On ignition, the combustible mixture in the neighborhood of the sparking plug ignited with great rapidity, causing further violent turbulence in the combustion chamber, so that the air and the burning mixture were intimately mixed, but not until combustion was well under way.

### Scavenging by the Use of Supercharger

Toward the end of the expansion stroke, the exhaust valve was opened in the usual manner and, shortly afterward, the ports in the cylinder walls were again uncovered, and the cylinder swept through and partially scavenged by the second charge of air compressed in the crosshead chamber; this second charge again entered above the piston in a more or less stratified form, the gas immediately above the piston being mostly air, while that nearer the top of the cylinder consisted mainly of exhaust products. On the upward stroke of the piston, the residual exhaust gases and part of the air were expelled through the exhaust valve, leaving the clearance space partially full of air. There was thus provided alternately a supercharge of air at the end of each suction stroke, and a scavenging charge at the end of each firing stroke, so that not only did the cylinder receive an additional charge of air over and above the charge drawn in from the carbureter, but a further supply of air was provided by the scavenging charge, which had the effect of replacing the residual exhaust gases in the combustion chamber with, at all events, a considerable proportion of pure air.

It will be seen, therefore, that, on paper at all events, the temperature of the cycle was reduced in two directions:

1. By lowering the flame temperature;
2. By scavenging during the exhaust stroke, while the air content was increased approximately 40 per cent, about 33 per cent by the supercharge and possibly 7 per cent by the scavenging.

It is obvious that the engine could be operated on either of two systems. Either a very rich charge could be admitted through the carbureter, providing sufficient fuel to combine with the whole of the air, in which case the mean pressure would be increased by 40 per cent, while the temperature of the cycle would still remain less than normal, thanks to the cooling effect of the scavenging charge; or a normal mixture could be admitted through the carbureter, in which case the air acted merely as a diluent, lowering the flame temperature and so increasing the efficiency of the cycle.

Before attempting any actual tests the engine, which was direct coupled to an extremely sensitive swinging-field electric dynamometer, was driven at its normal speed of 1500 r. p. m., and indicator diagrams were taken both from the crosshead chamber and the cylinder, the indicator being operated by linkage direct from the crosshead, in order to avoid any possible errors in synchronism.

ACTUAL INDICATOR DIAGRAMS TAKEN UNDER VARIOUS CONDITIONS.

Figs. 7, 10 and 11 with stratified charge. Fig. 14 showing admission of supercharge. Fig. 15, diagram from crosshead chamber engine driven by dynamometer. Fig. 16, diagram from crosshead chamber when running under own power. Fig. 17, diagram from working cylinder under normal running and when undercharging.

### Timing Admission of Supercharge

Fig. 15 shows the indicator diagrams obtained from the crosshead chamber after timing of the valves had been adjusted to give what appeared from the indicator diagrams to be the best possible results. In its original form the ports opened and closed 28 deg. before and after the bottom dead-center, and the inlet valve closed 10 deg. before the bottom dead-center; the motoring experiments, however, showed that it was unnecessary to close the inlet valve until after the bottom center was reached, since owing to the time lag there was found to be no tendency to blow back into the carbureter at speeds above 1000 r.p.m.

A very careful analysis was made both of the frictional losses and of the power absorbed in pumping both in the cylinder and crosshead chamber. These were found to be as follows, expressed in terms of mean pressure:

Total frictional losses, including windage losses .....	11.5 lb. per sq. in.
Fluid pumping losses in cylinder.....	3.5 lb. per sq. in.
Fluid pumping losses in crosshead chamber .....	4.5 lb. per sq. in.
Total friction and fluid pumping losses	
When running normally.....	15.0 lb. per sq. in.
When supercharging .....	19.5 lb. per sq. in.

Having arrived at what appeared to be the best possible timing from the point of view of volumetric efficiency, the actual tests were started toward the end of 1915. A Claudel carbureter was used, fitted with a needle valve in the jet, in order to adjust the mixture strength. The

Fig. 12—Section of supercharging engine. Above, section of crosshead chamber and intercooler used in a later engine

first results proved in some respects rather disappointing.

The main object aimed at, namely, the ability to work with a low mean mixture density, proved successful from the start, and it was found that the engine would run perfectly steadily with full supercharge when the charge admitted through the carburetor was rather on the weak side for normal running without supercharge. In spite of the extra work done in pumping on the underside of the piston, both the brake horsepower and consumption were improved by about 5 per cent when supercharging, the gain in indicated efficiency being nearly 10 per cent, which was in very close agreement with the theoretical gain. So long as the supercharge air was used only as a diluent and no attempt was made to increase the mean pressure beyond the increase due to the improved efficiency, all went well, but so soon as an attempt was made to raise the mean pressure to any substantial extent by enriching the mixture admitted through the carburetor, troubles began.

Although the flame temperature was lowered very considerably, as was proved by the gain in efficiency, the average temperature of the cycle was not apparently reduced to the extent that had been anticipated. When running normally with the most economical mixture the brake mean pressure obtained was 106 lb. per sq. in., corresponding to an indicated mean pressure of 121 lb. per sq. in. When supercharging with the same mixture strength the brake mean pressure rose to 112 lb. per sq. in. and the indicated mean pressure to 131.5 lb. per sq. in. When, however, any attempt was made to increase the mean pressure by enriching the mixture, severe detonation was set up which soon resulted in preignition.

At this time very little was known about the phenomenon of detonation, which was supposed to be merely a

premonitory symptom of pre-ignition and not, as is now realized, a perfectly distinct phenomenon, and often the cause but not the symptom of pre-ignition. At that period, however, the author, in common with most others, supposed that detonation and pre-ignition were kindred phenomena and that they were dependent solely upon the temperature of compression. This theory, however, did not appear at all satisfactory, for it was clear that the compression temperature must depend upon the ratio of compression and the initial temperature of the gases in the cylinder; since, however, the compression ratio in the cylinder was the same whether running normally or supercharging, and since the temperature of the supercharge was not high, while the effect of the scavenging was to replace the highly heated products of combustion remaining in the cylinder at the commencement of the suction with a certain proportion of comparatively cool air, it was difficult to believe that the compression temperature could be higher when supercharging than when running normally.

Lastly, the possibility that any uncooled part within the cylinder, such as the sparking plug points or the exhaust valve head, were reaching a higher temperature when supercharging was disposed of. A water cooled sparking plug was made up, and observation through the exhaust port showed that the exhaust valve, which was at a bright red heat when running normally, fell to a dull red when supercharging. Finally a stream of cold water was directed continuously against the underside of the exhaust valve head. Neither of these expedients proved of much avail. Although the author's belief that detonation and pre-ignition were closely allied and dependent upon temperature had by this time received a considerable shaking, he nevertheless decided to make every possible endeavor to reduce the compression temperature.

The direct passage of air from the crosshead chamber to the cylinder was cut off by a diaphragm, and the air was forced to travel through an intercooler consisting of a nest of small tubes cooled with a liberal supply of cold water, in order to insure that most of the heat of compression in the crosshead chamber and any conducted heat from the piston was removed before the supercharge entered the cylinder. This intercooler, which was destined to play an important and valuable part in the later experiments, had at this stage no effect whatever. Next, in order to increase the effect of the scavenging charge, the exhaust valve was set to open some 66 deg. early, or 10 deg. earlier than before, when, contrary to the author's expectation, the detonation and pre-ignition became far worse, so much so in fact that the engine would not run for any length of time on the supercharge at all, even with the weakest mixtures. This was somewhat of a surprise, and pointed to a new line of investigation altogether. The indicator was next fitted on the intercooler and diagrams were observed while running. It was found that when the exhaust valve opened 56 deg. early, the exhaust pressure in the cylinder at the moment when the ports were opened was slightly in excess of that in the intercooler, with the result that a very small quantity of exhaust gas passed out of the cylinder into the cooler and then back into the cylinder, followed by the air scavenge charge. When, however, the exhaust valve was set to open earlier this did not occur.

As a result of this experiment, the author came to the conclusion that the pure air scavenging charge, instead of flushing out and cooling the cylinder, tended to combine with the products of combustion, some of which were then not completely burned down to  $\text{CO}_2$ , and so assisted in the continuance of combustion during the exhaust stroke. Now the effect of passing some of the products of combustion out of the cylinder, cooling them below the ignition tem-

perature and then re-admitting them, was to prevent or, at all events, greatly reduce the after-burning, and also absorb the heat liberated by reassociation.

The next experiment tried was to open the exhaust valve 52 deg. early, with which setting the pressure in the cylinder was approximately 36 lb. per sq. in. when the ports were opened, with the result that a very substantial proportion of exhaust products passed through the intercooler.

Fig. 16 shows an indicator diagram taken from the intercooler under these conditions. With this setting it was found possible to increase the mean pressure to about 128 lb. per sq. in. on the brake, or 147.5 lb. per sq. in. indicated without detonation. This result appeared to clearly indicate that the lowering of the temperature brought about by eliminating the after-burning during the exhaust stroke had reduced the tendency to detonation and pre-ignition. A number of measurements were made of the heat carried away by the cooling water, both when running normally and when supercharging, and it was found that the proportion of heat carried away was about 6 per cent less when supercharging.

During the same period, namely, the latter part of 1915, the author was carrying out another series of tests on the use of kerosene, and great difficulty was experienced with detonation. The experiment was then tried of admitting along with the kerosene, vapor and air a small proportion of cooled exhaust gases, as is done in the case of coke oven gas-engines; this proved so completely successful in eliminating detonation, and with it all tendency to pre-ignition, that the experiment was tried of admitting a small proportion of cooled exhaust gas into the cylinder of the supercharging engine along with the fuel and air through the main inlet valve. This had the immediate effect of entirely eliminating all tendency to detonate, and it was found possible, by merely enriching the mixture, to raise the brake mean pressure to 140 lb. per sq. in. and the indicated to 159.5 lb. per sq. in., which was the highest limit attainable, the whole of the supercharge air being then required for complete combustion of the fuel. The quantity of exhaust gas admitted in this manner was extremely small, and yet its influence was remarkable.

#### Effect of Exhaust Valve Timing

The effect of this experiment was to raise doubts in the author's mind as to whether the after-burning during the exhaust stroke had really been the cause of the troublesome detonation. The exhaust cam was therefore set back to open the valve 66 deg. early, and a further test was made with cooled exhaust gas admitted through the carbureter, when it was found that the mean pressure could still be raised until the whole of the supercharge was saturated without being troubled with detonation, though a somewhat greater quantity of exhaust gas was required under these conditions. This proved that the general rise of temperature due to after-burning was not largely responsible for the detonation, and it seemed probable that the most significant effect of opening the exhaust valve late was that a proportion of the exhaust gases passing through the intercooler did not re-enter the cylinder during the scavenging period, but remained in the crosshead chamber, and were re-admitted along with the supercharge. As it might be rather inconvenient to admit exhaust gas through the carbureter in the case of a multi-cylinder aero engine, the possibility of admitting it along with the supercharge, and at the same time scavenging with cooled exhaust gas, was far more attractive. Accordingly, the exhaust valve was set to open 48 deg. early, so that the pressure in the cylinder was still about 50 lb. per sq. in. when the ports were uncovered, and probably nearly one-third of the total exhaust products passed through the intercooler, for the maximum pressure in the crosshead

chamber rose momentarily from 12 to 28 lb. per sq. in. Under these circumstances the scavenging charge consisted mostly of cooled exhaust gas with a relatively small proportion of air, while the supercharge consisted mainly of air, but with a small proportion of cooled exhaust gas.

With this setting the engine behaved satisfactorily in every respect, and both objects were attained, for on the one hand the engine could be run on a low temperature cycle, using the supercharge as a diluent, and so attain a very high thermal efficiency, and, on the other hand, the supercharge could, when desired, be used as an addition to the active working fluid, and a very high power output could be obtained, while of course any compromise was available between these two limits.

In Fig. 17 is shown a typical indicator diagram taken with the engine running normally and when supercharging—the fuel consumption and speed being the same in both cases.

#### The Effect of Certain Refinements

Having achieved the main objects the next step was to pay attention to refinements, and a number of minor improvements were made.

1. It was found, as might be expected, that the relatively early closing of the inlet valve caused some loss of volumetric efficiency, though this was compensated for to some extent, for when supercharging, the lower the pressure in the cylinder the greater the pressure-difference between that and the crosshead chamber, and therefore the greater the proportion of supercharge which entered. The inlet valve was already very large and the acceleration of the valve gear was very nearly up to the limit, so that little could be done in that direction; but the expedient of recessing the seating of the inlet valve, so that it formed a mask was adopted. The valve then acted as a piston valve, giving a very quick cut off when entering the recess or mask, after which it could be closed on to its seating at leisure; since the pressure-difference on either side of the valve was relatively small during the period of entry of the supercharge and the early part of the compression stroke, the leakage between the valve and the mask was very slight. This simple expedient proved successful, and has been used in all the tank engines and other engines the author has since designed, whether supercharged or not. The effect in the case of the engine in question was to increase the brake mean pressure when running normally from 106 to 109 lb. per sq. in. at 1500 revs. per minute, and when supercharging from 146 to 147.5 lb. per sq. in.

2. The intercooler, which originally consisted of a nest of very small tubes, was changed to a single flattened tube. The small tubes with their many soldered joints were a source of weakness, and since the function of the cooler had changed from that of cooling an already fairly cool air supercharge to that of cooling a relatively small quantity of very hot exhaust gas, it was obvious that a greatly reduced cooling surface would suffice.

3. It was found that the degree of stratification could be further extended and the economy and economical range of the engine could be increased by checking the rate of entry of the supercharge into the cylinder, and also by making the top of the piston concave, which further encouraged the supercharge air to form a layer over the piston. In order to check the rate of entry a baffle was provided in crosshead chamber near entry to intercooler.

4. The effect of cooled exhaust gases in checking detonation was so impressive that it was decided to raise the compression ratio from 4.7 to 5.1:1. Still higher compression ratios up to 6:1 were tried and, although the economy was improved in proportion to the compression, it was then found necessary to add so much inert gas to

Fig. 18 — Performance curves of supercharging engine. Full lines with supercharger in operation. Dotted lines supercharger not in operation.

the supercharge that the maximum power output was decreased.

With these modifications, the experiments so far as this engine was concerned were completed. The results obtained may be summarized as follows:

#### NORMAL RUNNING

Experimental supercharging engine: 110 mm. bore  $\times$  150 mm. stroke ( $4.33 \times 5.92$  in.). Compression ratio 5.0 : 1.

2200	30.5	133	.....	.....	.....	...	...

It may be argued that the normal power and efficiency of the engine were, compared with present-day practice, rather poor, but it must be remembered that the engine was designed nearly seven years ago, and also that the combustion head with valves in a side pocket was not of the form to give either the best power or economy.

It is obvious, however, that the percentage of improvement over normal running, both as regards power and economy, by the employment of a stratified supercharge will hold good whatever the normal performance may be.

The main object of all these experiments has been the application of the system to aircraft, the principal advantages being:

1. A very much greater increase of power in proportion to the increase of weight, the increase of weight being approximately 10 per cent, while the increase of power with fully saturated supercharge was nearly 40 per cent.

2. The method provides automatically a means of compensation for altitude. If on the ground the carburetor is set to give a normal weak mixture, then the whole of the supercharge air is acting merely as a diluent, giving improved economy and a slight increase in power. As the machine rises the flow of gasoline through the jet decreases as the square root of the density, while the weight of air decreases directly as the density; hence the mixture supplied by the carburetor gradually becomes richer and more and more of the supercharge is used as active working fluid, until at about 15,000 ft. the whole of the supercharge air is saturated. From ground level, therefore, to 15,000 ft. the power of the engine will decrease only as the square root of the density instead of directly as the density, as in the case of a normal engine, while throughout the whole of this range there will always be an excess of air present in the cylinder sufficient to ensure complete combustion, and the maintenance of conditions ensuring maximum economy.

3. In a multiple cylinder engine any lack of uniformity in distribution is corrected, since if any one cylinder receives a richer mixture than the others, instead of the fuel being wasted, more of the supercharge air in that cylinder is carbureted and the power output increased.

All the experiments referred to above were carried out during the years 1915 and 1916. During 1916, when the results had reached a reasonably satisfactory stage, an order was placed to build a twelve-cylinder supercharging engine of 600 b.h.p. At that date this was, to say the least of it, an extremely ambitious undertaking, but such an engine was actually built, though progress was necessarily very slow, and all official interest in the engine was lost and the engine had become thoroughly out of date long before its completion. On test, this engine actually developed over 700 b.h.p., but the main crankcase casting proved defective and developed serious cracks.

It will be apparent from the above description of the experiments that although the system of supercharging with a stratified charge can be made to give the performance that might be expected from purely theoretical consideration, yet it is rather sensitive. Much for instance depends upon the opening diagram of the exhaust valve and the closing diagram of the inlet valve, on the capacity of the intercooler and crosshead chamber, and on the position and area of the baffle, etc.

Throughout 1917 and 1918 the engine was entirely monopolized for carrying out tests relating to the tank engines, and since the armistice it has been devoted to carrying out tests on fuels, for which purpose the use of supercharging proved invaluable. A great deal of information has been obtained during the four years which have elapsed since the experiments were broken off, and many of the problems which puzzled the author at that time have now been cleared up. With the knowledge now available as to the phenomena of detonation, as to the important influence of combustion chamber design, and as to the treatment and influence of different fuels, very great improvements could undoubtedly be made. It is hoped shortly to build a larger and more up-to-date experimental engine on generally similar lines but embodying all the most recent information.

SWITZERLAND imported the following quantities of automobiles in metric tons during the years mentioned: 1913, 1059 metric tons; 1919, 5606 metric tons; 1920, 11,747 metric tons. The imports of automobiles into Switzerland during the same years were as follows: 1913, 2171 metric tons; 1919, 2668 metric tons; 1920, 1801 metric tons. It will be noted that not only are the Swiss exports of automobiles much smaller than the exports, but the exports have actually declined since 1913.

# Economy and Efficiency Increased by New Final Assembly System

Many assembly difficulties were surmounted in installing the new final assembly system described here. The equipment had to be adapted to buildings already in use. High efficiency has been attained despite the necessity of turning corners. Methods of equipment are discussed.

By Norman G. Shidle

**S**OMETIMES a production layout can be designed before any structures have been built in which to house it. In such cases the buildings can be erected to conform with the most efficient production system as determined from a study of the theoretical possibilities. This situation is not common, however, in actual manufacturing. More often the production engineer is compelled to adapt his system and methods to a building or set of buildings already erected and perhaps previously used for some other purpose.

Because this latter case is the more usual, a plant in which the adaptation has recently been made with special success furnishes an interesting example for study. Although compelled by the construction of the buildings to take a number of turns, an efficient final assembly system has been put in operation at the Franklin Automobile Company and has already proved its economy in the few months since its installation.

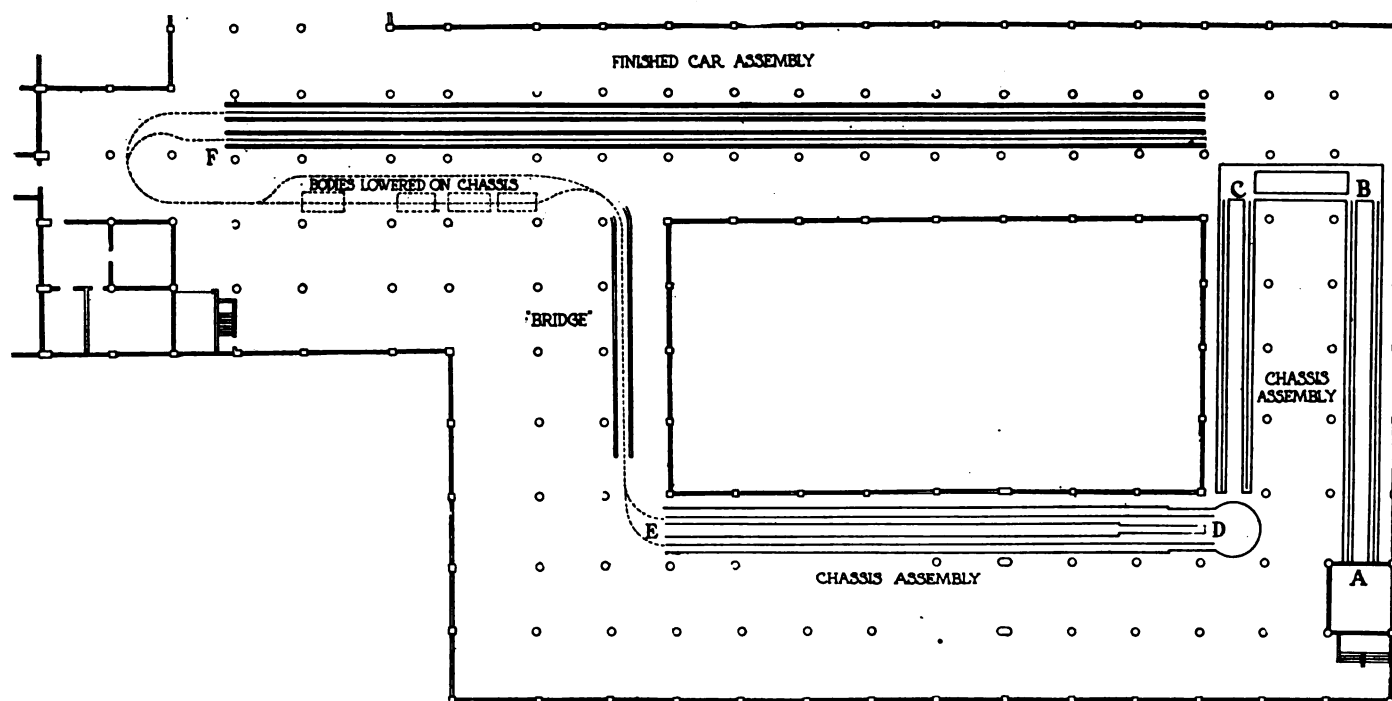

This final assembly system is divided into two parts, namely, the chassis assembly and the finished car lines. The mechanical conveyor equipment for each line is different, the chassis conveyor being a single chain, and the final car assembly conveyor being a two-belt conveyor operating

over rollers. The chassis rests on trucks while on the chassis assembly line, the truck hooking on to the conveyor. When the chassis reaches the finished car line, however, the wheels rest on two moving belts.

A feature of the Franklin practice of special interest at present is the effective utilization of excess equipment with the consequent reduction in unit costs. The conveyor equipment on these final assembly lines is capable of handling over 100 cars a day, while production at present is being held at forty a day. There are two conveyor lines for the chassis assembly and two for the final car assembly, but only one of each is in active use.

The excess equipment, however, is being efficiently used, as will be brought out in the following detailed description. This point is emphasized, however, because it is of great importance just now in many plants. The methods used here may furnish ideas for similar methods elsewhere, whether in connection with assembly or other production work.

The chassis assembly line begins at point A indicated on the floor plan shown in Fig. 1. The front and rear axle and spring assembly is brought to the assembly line in completed form. A few minor operations are completed

Floor plan of chassis and final car assembly layout.

before the frame is placed on the conveyor. These include such operations as assembling bearings to shaft, shaping brake bands, filling and assembling grease cups, assembly ball and spring box steering gear connection, assembling end of emergency brake rods, etc.

Two specially constructed trucks carry each chassis as it moves along the conveyor. These trucks are so constructed as to hold the chassis some four feet off the ground during the first few operations and then to allow the lowering of the chassis to a height of about two feet for the remaining operations. Detailed drawings of one of these trucks are shown in Fig. 2.

The first man performs several operations after the frame has started to move on the chassis conveyor. He assembles the hood holder hinge, bolts for running board, battery box, front and rear bolster bolts, elevator bolts for muffler. Then by means of a power hoist he turns the sill over and it goes on to the next set of operations. Fig. 3 shows the beginning of the chassis assembly line.

While in inverse position, the following units are assembled to the sill: running board bolts, muffler, muffler tail pipe, trunnion support brackets, foot lever springs. The gas tank bracket holes are reamed at this point. The sill is then returned to its upright position.

Two men work together on the next set of assembly operations. They put into place the emergency brake lever, the gas line, horn bracket, battery box supports, emergency brake rod, and the running board.

After the sill blocks have been assembled, the rear axle is put into place and the cardinal shaft is lined up. The sill is returned to its upright position after the rear axle has been assembled.

Fig. 2—Special trucks on which chassis is carried over conveyor line

This completes the first stage of the journey. The chassis has then reached the point marked "B" on the floor plan. The trucks are loosed from the conveyor chain and following grooves in the concrete floor, which serve as tracks, is pushed across to the second part of the chassis assembly conveyor line. During its trip across, as shown in Fig. 4, the front and rear wheels are assembled together with the battery box cover, the gas tank, and gas tank filler. The trucks are then caught on the next conveyor line, which begins at the point marked "C."

An adjustment operation is the first one on this line. Two men line up and adjust the emergency brake bands and assemble the gas tank filler. The engine is then put into place. In bringing the engine to this point in the assembly line, a part of the excess equipment, previously referred to, is being utilized. The engines come from the sub-assembly to the far end of the final car assembly line near the point marked "F" on the ground plan.

Since only one of the conveyor lines is being used at present, the engines are transported the length of the building on the second final car conveyor. Thus they are brought to the point "C" on the chassis assembly line at which they are put into place. When both final car conveyors are in use, a separate conveyor will be used for carrying the motors to the place of assembly. Fig. 5 shows the motors on one conveyor and the final car assembly on the other.

After the motor has been aligned and bolted down, the trunnion support rod is assembled, the spark plugs are set and the H. T. wire conduit put in place. The chassis then

passes to the next workers, who line up and bolt down the transmission. They also assemble the foot levers to the transmission rail, put on the steering device and tighten the spark-plugs.

A group of three men performs the next operation, which consists of assembling the front drive shaft flange, placing ball on change gear lever handle, tightening valve caps, assembling battery box holder bolts, fastening spring to foot lever, and assembling engine boots to engine base. In the next operation the starter cable is assembled and the lower flywheel guard adjusted.

The next operation brings the chassis to the end of the second leg of its trip. Here three men perform a number of minor adjustment operations, such as reaming holes and shaping lower flywheel guard, lining up the wheels, assembling diagonal rod to steering device, etc. These operations are preparatory to the first engineering inspection. This inspection is very minute and every detail of assembly and adjustment is carefully checked up. All defects and troubles are listed and the list is passed on with the chassis to the next man, whose task it is to make the necessary repairs and readjustments before the chassis proceeds farther.

When these repairs have been finished the car is ready for the third stage of its journey. As it comes off this conveyor the trucks are removed, and the chassis is run on to a round table, as shown in Fig. 6. This round table swings the chassis around the corner and in position to catch on the third leg of the conveyor system at the point marked "D."

Here the upper flywheel guard and the diaphragm are assembled, the gas line is straightened, the carbure

ter throttle lever put in place, and the junction box is assembled to the sill. The next operation is performed by a group of three men and consists of assembling the front engine jacket, oiling all running parts, assembling pivot bolt cups, knuckle bolt, muffler exhaust pipes and muffler exhaust pipe bracket. Then the drain cock handles are assembled complete, the muffler exhaust stamping box is tightened, the heater pipes are assembled, and the linoleum is fitted and tacked to the chassis.

A second engineering inspection, followed by the necessary repairs and readjustments, then takes place. This is followed by a final engineering inspection with other repairs and readjustments.

Necessary painting is then done of the top of the chassis, the hub caps are put on, the front guards are assembled to the running board and a few minor drilling operations are performed. The chassis is run off the conveyor line at the point marked "E" and on to "bridge," which permits the accomplishment of necessary work underneath the car. This "bridge," shown in Fig. 7, is equipped with a power conveyor which carries the chassis from the floor level. While on the bridge the front guards are assembled to the sill, the seat pedals are finally assembled, and the necessary painting underneath the car is done. The running board shields are assembled and the completed chassis is run off the bridge and into position for receiving the body as indicated by the lines on the floor plan.

This completes the twenty-one operations on the chassis assembly line. Forty-five men are required for the regular work on this line, while four utility men are employed for

Fig. 3 (Top)—Beginning of chassis assembly line

Fig. 5 (Center)—Showing utilization of second final car assembly conveyor for transporting engines to assembly point

Fig. 7 (Bottom)—Chassis pulled on to "bridge" by power conveyor

Fig. 4 (Top)—First turn in assembly line; wheels assembled at this point

Fig. 6 (Center)—The round table at the second turn in the assembly line

Fig. 8 (Bottom)—Beginning of final car assembly line

general work and for filling in gaps. There is also one working master workman, bringing the total men on the chassis line to fifty. The conveyor on the chassis line moves at the rate of 1 2/3 ft. per minute. This produces the quota of forty a day in 8.7 hours.

The body is lowered on the chassis by means of an overhead crane. The horn wires are assembled to the decks, the horn and headlight wires are attached to the sill, the wires are packed under the cowl and the upper carburetor heater wire is connected. The body is then assembled to the chassis. The chassis with the body attached is then run on to the final car assembly conveyor, Fig. 8.

There are other detailed operations in connection with the body work, but since a change in methods is contemplated in the near future, these details need not be discussed. Twenty-eight men are used in the body assembly work. A plan is now under way to utilize the extra chassis conveyor for the body assembly work. This would put the body assembly on a progressive assembly basis and make for greater efficiency, while there would be no added equipment cost since only equipment now idle would be utilized in making the improvement.

The chassis and body now start down the final leg of the assembly run, beginning at the point marked "F" on the plan. The next operation is that of assembling the rear guards and sill finishing strips and fastening the running board shields to the body. From this point to the end of the final car line there are twelve more operations to be performed. The first of these consists in nailing back curtains to the body, assembling the back curtain complete and assembling the headlight brackets.

This is followed by the toe and floorboard assembly. Next the rear rocker carpets, upholstering, seats, bags, etc., are put in place and the mud apron and headlights are attached. The steering device clamp is next attached, followed by the front and rear mats, the foot lever pads, the dash air control, and the needle valve. This operation is completed by the assembly of the oil can holder, the connecting of the speedometer cable and transmission and the placing of the bell crank.

The next operation includes the assembly of the vacuum tank hush pipe, suction yoke heater, and dash control. The wiring is completely assembled after this and the necessary painting is done. Next the hood is roughly fitted to the dash and the hood V blocks and hood locks are located and assembled. The assembly of hood hinge pins and engine jacket filler constitute the next operation, while the last operation before the engineering inspection consists in finish fitting the hood complete. The usual repairs and adjustments then follow the engineering inspection. The car is then given a final engineering inspection and is practically at the end of its trip. Final repairs and adjustments remain to be made, while a few minor assembly operations, such as assembling brackets on hoods, etc., complete the assembly process.

There are sixteen operations performed on the final car assembly line, forty-four men being used on this job.

This description completes the mechanical phases of this newly installed assembly conveyor system. The results attained have been excellent and are dependent partly upon this mechanical equipment and partly upon the human phases of the production methods in use at this plant.

Since the introduction of this conveyor system a few months ago there has been a decided increase in the production per man. Grouping together the chassis and the final car assembly system, some thirty less men are being used than heretofore to produce the forty car a day quota. For the chassis, body, and final car assembly there are now 131 men used.

There are other factors besides that of the regularity of effort enforced by a moving conveyor, however, which

operate to increase production per man. One of these factors is the goodwill which the management has engendered among the workers.

Because of the unemployment situation there has been an increased individual efficiency noted in practically every plant. This has been the case at Franklin as well as elsewhere. Not only has actual working efficiency increased, but regularity of attendance has become much more common. Every man is there every day, ready to work all day unless something very serious keeps him away. It is not necessary to carry as many extra men to insure a given production.

An unusual feature of the results at this plant is that production per man was increased when the men were taken off piece work and put on a day work basis. The moving conveyor, of course, maintains a scheduled output, but the experience of increasing production when changing to a day rate basis is not common. It is true, however, that wages have not been cut at this plant since the industrial depression set in and the men on these assembly lines are earning as high wages as at any previous time. Thus far wages have been maintained through an increase in individual efficiency and closer study of detailed production factors.

Another factor which should be mentioned is that the men are encouraged to make suggestions for improvements in production methods. Prizes are offered for adopted suggestions and the pictures of those presenting such suggestions are given prominence in the company house organ. There have been several such suggestions adopted in connection with these assembly lines. While the suggestions related to minor phases of production, they each made for greater efficiency. In addition to the actual value of the suggestions, moreover, must be considered the potential value of the increased interest in the work thus aroused among all the workmen on the line.

It is through the effective correlation of the mechanical and human phases of production activity that the excellent results have been recorded at this plant. It is an achievement for an automobile plant to be producing at this time two-thirds of the highest production ever recorded for the factory. The frankness of the management with the men, the real facts and information presented to the men in the company house organ, and the honest attempt to give the workmen a fair deal in every way has undoubtedly played an important part in making possible that achievement. All increases in production efficiency are not made in the office of the production manager.

**V**ARIOUS large bodies interested in the use of automobiles and motor trucks in Germany recently had a meeting to organize with a view of combating a proposed heavy increase in the tax on automobiles. The organizations represented were the Automobile Club of Germany, the General German Automobile Club, the German Brewers' Union, the Association of Automobile-Using Physicians, the Association of Automobile Dealers, the Association of Carriage and Automobile Body Builders and the Association of German Motor Car Manufacturers. Recently automobile and motor truck owners have not only been compelled to pay heavy annual registration fees, but in many instances counties and even communes have levied taxes on cars and trucks. Against this practice it is urged that if it were not for the use of the motor truck many industries would show less profits or no profits at all and hence would not be able to bear such heavy tax burdens. It is not planned to oppose any increase in automobile taxation, but merely to work against the imposition of prohibitive taxes which would prevent the creation of new wealth through transportation.

# Progressive Production Methods Applied to Body Building

The application of quantity production methods to body building is limited by the dependence of the body builders on car production conditions. A high degree of efficiency is possible, however, as is evidenced by the system described. Kiln drying lumber is an important phase.

By George J. Mercer

**W**HEN a body building plant grows to a large size it shares with other industries the necessity for quantity production methods, together with the maintenance of high quality of product. Under such circumstances it is often advisable for the body manufacturer to control rather directly a large part of his sources of material supply.

Certain features of body building practice, however, place a definite limit on the extent to which quantity production methods and automatic machinery can replace human skill and effort. A great deal of hand work is necessary in the actual production of bodies. Then, too, body production must always depend for its rate of production upon the status of car production. The body plant cannot go forward with production until the car factory is in operation. Moreover, the body plant usually must be equipped to handle a variety of designs and materials and to provide bodies for different kinds of chassis. Consequently, it is often necessary to change the set-up of tools and equipment from season to season.

While the dies and jigs in the shop must be changed for each design, a large part of the raw stock, such as lumber and sheet metal, can be bought in quantities and stored ahead, since it is purchased in sizes that are suitable for almost any model.

An examination of the methods used in producing several body models for Chevrolet, Reo and Oldsmobile at the Hayes-Iona Company furnishes an excellent illustration of body building practice. The bodies made at

this plant include the Chevrolet FB sedans and coupes, Chevrolet 490 sedans and coupes, Reo sedans and coupes and Oldsmobile sedans. The daily capacity of the plant is 65 completely painted and trimmed bodies. The accompanying photographs will aid in describing the routing of work and the progressive production system used in maintaining this production.

It is common knowledge that properly dried lumber is essential to the proper construction of composition bodies. Even though lumber be of the highest quality, it will shrink away at the joints and cause trouble during machining and assembling operations if it has not been properly dried. Such shrinking causes the frame to be weak and unstable, thus putting on the panels undue distortion strains.

Thus adequate kiln facilities are of primary importance, while their location as related to the mill and supply source is a production factor necessary to consider. Fig. 1 shows the kilns used at this plant. Kilns line both sides of the central track, which connects the lumber pile to the mill room.

Two kinds of kiln are used, the compartment kiln and the progressive kiln. In the compartment kiln the moisture is forced through the planks when they are first put in. An attendant watches and records the daily condition of the drying process. In the progressive kiln tiny jets of steam are in continuous operation at one end of the kiln. The planks go in at this end and daily progress toward the opposite end. By the time they have

Fig. 1—Dry kilns

Fig. 2—Mill room, showing cut-off saws

Fig. 3—Mill machine room, showing band saws

Fig. 4—Mill finished stock room

passed clear through the kiln they are dry and ready for removal.

The capacity of these kilns is 18,000 feet per day. The mill room requires approximately 300 feet for every closed body, though the exact requirements vary with different models.

The mill room, shown in Fig. 2, is adjacent to the kilns. In the mill room the planks are cut into lengths for machine operations. The band-sawing operation is shown in Fig. 3, while Fig. 4 shows the dressed stock ready for the frame assemblers. Fig. 5 shows the frames completely assembled and ready for the panelers. The following machines are shown in Fig. 3:

- 4—Swing cut-off saws.
- 4—Band rip saws.
- 3—Planers.
- 2—Automatic feed jointers.
- 2—Linderman machines.
- 1—Double end tenoners.
- 4—Single end tenoners.
- 4—Multiple boring machines.
- 3—Single boring machines.
- 3—Hollow chisel mortisers.
- 1—Chain mortiser.
- 4—Routers.
- 3—Stickers.
- 8—Band saws.
- 8—Mitre saws.
- 10—Shapers.
- 1—Sill shaper.
- 1—Sill gaining machine.

Fig. 5—Framing department

Fig. 6—Finished stock room

- 2—Screwing machines.
- 2—Sand belts.
- 1—Band resaw.

Many of these machines are motor driven, and others are being similarly equipped as rapidly as conditions warrant the change.

Figs. 6 to 16 illustrate various phases of the progressive production system. Each photograph is adequately explained by its caption, and a study of the group in the order indicated will bring out the various steps in production.

The actual work of production starts simultaneously in the mill department and in the metal stamping and forming department. The layout of the department may be likened to an inverted letter Y, the two departments named being at the extreme ends of the angle. The paneling department is at the apex of the angle. From this point onward the various departments are laid out in a straight line.

Drawings and specifications are made up, of course, in the engineering department. From here they are forwarded to the sample and tool rooms. There the patterns, templates, jigs and forms are made and tested. They are then released to the production departments that require them.

Raw metal stock room is shown in Fig. 7. Here enough metal is stored to produce 50 closed bodies per day. The metal is chiefly 22 gage, approximately 1/32 in. in thickness and weighs 1½ lb. per square foot. Each body

Fig. 7—Metal raw stock room. Fig. 8—Machine used for forming metal shrouds when order is not large enough to warrant making of dies. A form, the shape of the shroud, is placed over a hydraulic ram, and the sheet is laid in this form. The ram forces the form up into the sheet.

Fig. 9—Metal department

Fig. 10—Large metal presses

Fig. 11—Finished stampings

Fig. 12—Forming overlay of touring body doors

Fig. 13—Paint spray booths and drying ovens

Fig. 14—Cutting operation in trim department

requires for paneling and waste about 240 sq. ft., or 300 lb., of metal. The following machines perform the metal work required:

- 7—Power hammers.
  - 2—Square shears.
  - 3—Rotary shears.
  - 10—Drill presses.
  - 2—Sets metal rollers.
  - 2—Metal band saws.
  - 4—Spot welders.
  - 2—Heading machines.
  - 7—Acetylene welding outfits.
  - 2—Metal breaking machines.
  - 1—Threading machine.
  - 1—Rattler.
  - 2—Folding machines.
  - 25—Air grinders.
  - 22—Metal forming and punch presses, varying from small punch presses to large forming presses used for the large body panels.
  - 1—Large hydraulic press for shrouds and back panels.
- The work is routed as follows:
1. Wood parts are brought from the machine room or frame room, where first assembly takes place, to the paneling room.
  2. The metal stamped panels are assembled in the paneling room.
  3. The shell is then forwarded to the door hanging room where the doors are assembled. The body is then ready for its first coat of paint.

Before the paint is applied the surface of the panels is treated with a bath of Dioxodene. This preparation

is applied with a brush and is then washed off with water. Live steam is then turned on the body and is later dried with compressed air. Thus all corners and moldings are cleaned thoroughly. Since Dioxodene is detrimental to paint, the cleaning process must be performed very carefully. This method of cleaning has superseded the use of the sandblast, because the sand occasioned trouble in the hinges and other parts. The sand cleaned the rust off satisfactorily, but added another trouble more difficult to overcome.

The paint spray booths and drying ovens represent a saving in time of from 40 to 80 hours over methods formerly used. The heat is applied from 160 to 180 deg., and the time consumed in completely painting the body is seven or eight days. The painting process is carried as far as the first color varnish. The final rubbing down and varnish is put on by the customer after the shipment has been received at the home factory.

From the paint shop the body goes to the trim shop and from there to the final assembly department, where the glass, windshield and mountings are put on. Then, after a final inspection, the bodies are ready for shipment.

**T**HE Trompenburg Automobile Works of Trompenburg, Holland, manufacturers of the Spyker six-cylinder car, have secured a license from the Mathis Automobile Co., Strasbourg, Alsace, for the manufacture in Holland of the small four-cylinder 2.36 x 3.94 in. Mathis car.

# A Definite Step in Motor Transportation Educational Work

A course at Syracuse University is taking up motor transportation problems from the business and economic viewpoint. The students make practical investigations as well as consider fundamental factors. Such courses may be nuclei of valuable data for the industry in the future.

**C**ONSIDERABLE attention has been attracted to the educational features of highway transportation through the formation and efforts of the Highway and Highway Transport Education Committee. This body, formed through the co-operative efforts of the automotive industry, the Government, and other interested agencies, has concerned itself in the encouragement of highway transport engineering education, both in the way of engineering courses and of general appreciation of the possibilities and advantages of highway transportation.

The necessity for trained men understanding the problems of highway engineering and transportation has become very apparent and various efforts are being made to provide such men. Most of the definite educational efforts have thus far been concerned chiefly with the engineering phases of the problem. Michigan, Pennsylvania, Harvard, Minnesota, and other universities have given courses, of greater or less length, along this line.

There is another important side, however, to the problem of motor transportation. An almost virgin field is presented for research concerning actual transportation costs, the economics of truck performance under given circumstances, in given industries, and under given load conditions. A few truck companies are doing extensive work along these lines in connection with their own product. These efforts, while of rather broad scope in a few cases, must necessarily be aimed directly at immediate truck sales. The data and experience gained by the various companies will aid materially in developing the literature and scientific information necessary, but it will probably be necessary to look to some more disinterested agency for the broader phases of research.

Because of this situation the course in transportation being given at Syracuse University is worth the attention of the industry. This course begins its second year in the fall of 1921. The chair of transportation in the School of Business Administration at Syracuse University was endowed by H. H. Franklin, and the study has gone forward under the direction of Prof. Charles Lee Raper, who has had a very extensive experience in transportation work.

This course has approached the problem of motor transportation from the business and economic viewpoint. It has endeavored to establish the relation of the motor vehicle to other forms of transportation, to determine the cost of operating motor vehicles under certain conditions, and to establish the economic value of the truck as a transportation unit.

The entire course takes up four main topics, namely,

1. Railroad transportation.
2. Water transportation.
3. Motor transportation.
4. Public utilities.

These major topics are supplemented by specific studies in the following:

1. Traffic.
2. Rates.
3. Ports and Terminals.

While the automotive industry is, of course, chiefly interested in the motor transportation phase, the above outline indicates that the function of the motor vehicle is being considered in its proper relation to other forms of transportation. There is a distinct practical value in this, since the field of the motor truck must be defined either in competition or in co-operation with that of other forms of freight and passenger transportation.

In the motor transportation course the principles of motor transportation are discussed, together with its industrial significance. Considerable time is given to a study of truck operating costs. In discussing operating costs, the first thing is to analyze the factors which enter in to making costs. These factors are outlined and discussed, and an attempt is made to establish their proper relation to each other.

The students are required to apply this analysis to some specific case. Last year a number of interesting papers were written by the students concerning truck operating costs and the use of motor trucks in specific industries. One paper, for instance, dealt with the costs, methods of routing, and operating a fleet of trucks for a large baking concern in Long Island. The fleet operated over a distance of some 60 miles and presented an interesting and complex problem for analysis.

The course also takes up the field of the motor truck in a general way. The possible uses in a city, in territory surrounding a city for 50 or 75 miles, and in rural territory. All the factors affecting truck use under these varying conditions are discussed and the field of the motor truck as a transportation unit is fully analyzed.

The relation of truck costs to the various types of highway construction is also taken up, and the students are furnished with the results of the best available tests along this line. Great care has been taken, however, in every phase of the work, not to lay down as fixed rules and as final information any data or factors concerning which there is still considerable debate.

Since this is the case with much of the data concerning motor transportation, the course presents much material for discussion and has aroused a great deal of interest. Such discussion, based upon actual investigations and studies by the students, is an excellent thing for the cause of truck transportation.

Our colleges and universities have furnished the basis for much industrial research in the past. Leaders of industry have come to recognize the potential value to industry of the professors and investigators in our educa-

tional institutions. It is to be hoped that this course and those conducting it will in the future furnish to the automotive industry much valuable data, based upon extensive research and investigation. Professor Raper is intensely interested in the motor transportation phase, and can be counted upon to visualize the big problems of the industry and to push forward needed research in this field.

Such research cannot be accomplished in a few days or a few months, but the value of such centers of potential information as is furnished by this course should be recognized by the industry. In the meantime, young men are being turned out who have a broad conception of the

field of motor transportation; who are certain to spread the gospel of better motor transportation methods whether they directly enter that field or go into business using trucks as part of its transportation equipment.

Next year several older men are going to Syracuse to take this course. One man, for instance, is expected who has had charge of a large fleet of trucks in the Middle West for several years. Men of this kind, working under the direction of a competent instructor, may be expected to give much for the advancement of accurate knowledge and data concerning the business and economic phases of motor transportation.

## Shuler Front Wheel Brake

**A** DESIGN of front wheel brake has been evolved by the Shuler Axle Mfg. Co. and embodied in a front axle for trucks manufactured by that concern. Heretofore front wheel brakes have been spoken of mainly in connection with passenger cars, but it is obvious that they possess considerable advantages when applied to trucks, especially in the case where the truck is used to haul trailers behind it. Powerful brakes are really essential on trucks, because so many of them are operated in the congested sections of the large cities where the chances of collision are great.

The Shuler brake is of the internal expanding, toggle-operated type. Adjustment required to compensate for wear of the brake lining is made by changing the length of the toggles. The links are hinged to lugs riveted to the brake band near its ends, and they also connect to a two-armed spider, the hub of which is adapted to slide up and down on an extension of the knuckle pin. The knuckle pin is keyed to the knuckle with a tapered key and turns with it, the upper and lower members of the axle yoke being suitably bushed. The bushing in the upper member is provided with a head forming a face cam or end cam, and the brake lever arm, the hub of which is inserted between this bushing and the two-armed spider, is formed with a similar end cam engaging with the former. Any pull on the brake lever causes it to turn around the pivot axis and at the same time to rise on the knuckle pin, carrying with it the two-armed spider and spreading the ends of the brake band through the intermediary of the toggle links. When the front wheel is swung around in steering, the brake lever with its end cam, and the bushing in the steering yoke remain stationary, and the brakes, therefore, are not affected by the steering action.

The axle to which these front wheel brakes are fitted is of 2 and 2½ tons capacity. It has a drop forged I-section center of .30 to .40 per cent carbon steel, heat-treated. Chrome nickel steel is the material from which the steering knuckle is forged, and the steering arms are of the same material. The hubs are of malleable iron and the caps and flanges of pressed steel. The materials used for the brake parts are as follows: Knuckle pin, 3½ per cent nickel steel; drum, pressed steel; band, strip steel rolled to a true circle and lined with asbestos fabric; cam bushing, cold drawn steel, carbonized, hardened and ground; brake lever, No. 1035 S. A. E. steel, drop forged and heat-treated; toggle eyes and links, drop forgings; band fittings, malleable iron. The cam surfaces are true helical surfaces.

## Viscosimeter Conversion Chart

**A** USEFUL chart for converting readings on one make of viscosimeter to readings on other makes of instrument is contained in *Lubrication* for May, 1921. Use of the chart is fully explained. Saybolt, Redwood, Engler and Barbey curves are included and conversion from one to the other scale made as convenient as possible. The scale used is one of kinematic viscosity which is defined as the ratio obtained by dividing the absolute viscosity by the specific gravity at the same temperature.

Another issue of the same publication quotes results of tests recently published by the Advisory Council of the British Department of Scientific and Industrial Research, which show that the viscosity of oils increases rapidly with increase in pressure. In the case of some oils tested increase of pressure to 5000 lbs. per sq. in. increases the viscosity 125 per cent.

Sectional views of Shuler front wheel brake

## Improvements in Fuel Utilization

Editor, AUTOMOTIVE INDUSTRIES:

What impresses me most about this matter of petroleum fuel conservation is the rather minute effect which all our discussions and research have upon the policy of some of the engineering departments of the automobile industry. In general, all car makers would like to get better gasoline mileage, provided the carburetor alone will do it, but many will not change their stereotyped designs nor concede even 1 per cent in any detail of power or speed demonstration to lower their fuel consumption. Similarly it appears that the lower priced car manufacturers at the present time can scarcely afford to spend very much for better carburetors or for new tooling equipment to produce changes of construction which would give better efficiency. To me it appears that a general improvement will come only when forced by a pronounced increase in the price of fuel. The situation is somewhat different with regard to trucks and all the makers of the better class of trucks are really interested in obtaining the most efficient operation possible.

The various means of increasing fuel efficiency being applied in the industry, which I have been able to observe, may be subdivided under three heads: Lowering the fuel consumption by change of engine cycle, by improving the mechanical efficiency and by improvements in carburetion and manifold design.

### Changes Affecting the Engine Cycle

Under changes in the engine cycle would come raising the compression, with some special means of avoiding detonation. Raising the compression seems to improve the fuel efficiency even more at part throttle than at full load, possibly because it not only gives a greater expansion ratio but also in the former case reduces by a greater percentage the volume of exhaust diluents in the attenuated throttled mixture.

The methods of avoiding detonation are as follows:

1. Delayed intake valve closing, which requires careful experiment to avoid loss of power and give proper speed graduation.

2. Injection of water as used on some tractor motors, which is an annoyance because the water consumption is almost equal to the fuel consumption.

3. Injection of cooled exhaust as proposed by Ricardo. I have had little success with this latter method with our

heavier fuels which seem to burn inevitably with a carbon residue, because introduction of exhaust increases very rapidly the carbon deposits in the cylinder. I know of no instance of successful use of this method.

4. Control of the carburetor throttle according to speed in such a way as to restrict the charge slightly at low speeds, when detonation is most apparent and objectionable. This method is somewhat similar to that of delayed intake valve closing and is being experimented with by a few companies at the present time.

Another change affecting the nature of the indicator diagram is in the use of some method of control other than the carburetor throttle, that will avoid the suction pumping loss. I refer to the loss on a part load indicator card as indicated in Fig. 1. The most obvious way of eliminating this loss is by reducing the torque by early closing of the intake valve, giving a card as shown in Fig. 2, or late closing of the valve, giving a card as shown in Fig. 3. Instead of actually shifting the camshaft timing a motor driven rotary valve might be placed in the intake manifold. (See Fig. 4). This pumping loss is appreciable on the average car only below 25 miles per hour smooth level road driving and I doubt whether this complication would justify itself.

So far I have observed no definite improvements in engine operation due to changes which should affect the turbulence of the mixture in the cylinder. That is, we know of no especially successful application of the knowledge recently gained regarding this phenomenon.

### Mechanical Improvement

The most obvious step to raise the mechanical efficiency of the motor in average driving is the use of the four-speed gearbox. I have heard of few passenger car makers who are changing to a four-speed gearbox on this account, but have heard that certain makers of truck transmissions are planning to bring out an increased number of gear changes. Simplification of the gear shifting operation has received some attention and is worthy of more.

Reduction of the engine friction can be best brought about by careful manufacture, with improved lubrication, and with modified piston design, whereby quietness when cold can be obtained along with free running when hot. There is some activity in regard to pistons, but I think the engine makers are now more pressed to reduce their costs than to improve their construction. There is without doubt a very considerable percentage of loss in the

Indicator cards showing effect on pumping loss of valve timing at a load and engine speed equivalent to about 20 m.p.h. level road driving

Fig. 4—Diagram of rotary manifold valve arranged to control effective time of charge admission and give a card such as that in Fig. 2

drive of many cars, which could be eliminated by better design. Part of this loss is in transmitting the power from the wheels to the road, when the roads are rough; for instance, on one car I occasionally drive, the rear axle is hung in such a way that the car cannot go over a bump without sliding the wheels, or suddenly decelerating the car or the engine flywheel; actually a little of each seems to take place. I am inclined to believe that a number of the axles in use to-day have considerably more friction, with the weight of the car on them, than we think; at least there is a very great difference in the drawbar pull per ton required to move different cars.

#### Improvements in Vaporization and Distribution

The application of exhaust heat and maintenance of adequate mixture temperatures, as outlined in the recent S. A. E. Fuel Committee Report, seems to give practically the full efficiency possible with present engines, under steady running conditions after the engine is warmed up. In cold weather, however, there are long periods when the manifold temperature is not adequate and at such times there is considerable fuel waste. Also, with the manifold

design recommended in the S. A. E. Fuel Committee Report, there is a small percentage but considerable amount of fuel going to the motor in the liquid state, as brought out by Mr. Dorris' paper and the discussion following it at the recent Summer S. A. E. Meeting. Mr. Dorris has shown one way of taking care of this.

We are just completing experiments with a fuel heater to be connected between the intake manifold and the carburetor. This device separates the unvaporized fuel from the mixture and throws it down into a separate chamber on a thin copper floor over the exhaust. The fuel then comes out of this chamber as a white and greasy fog. As might be expected, there is considerable saving in fuel, no crankcase dilution and reduced carbon deposit, but the most noticeable effect is that the engine fires very much more smoothly under adverse conditions such as usually exist in the average car after the unskilled driver has had it, while, for example, improperly spaced ignition points, slightly leaking valves, etc. With this system the engine operates satisfactorily on heavier fuel than kerosene, except for the trouble of detonation. As pointed out at West Baden, with this system there is no problem of distribution or of proper manifold size; the intake manifold can be cast in the cylinder block as large as desired and of any contour that will make a smooth external shape. Before heavy fuels can be regularly used, however, we must solve the problem of detonation, also of special means for starting.

Regarding the carburetor as a metering device, there is scarcely room for pronounced further improvement. Some engineers seem to be quite definitely convinced that the coming development is toward higher motor speeds and smaller displacements and that this will change the trend of carburetor design. Irrespective of the carburetor proposition, I believe this idea is wrong, but in any case, I am quite sure that so long as the present type of motor is continued, there will be room for detail improvements only in the better types of carburetors now used. The carburetors used on some of the lower priced cars could be considerably improved.

I know of but few makers who have made any effort toward furnishing replacement parts to improve the fuel efficiency on cars already out. This is a very important matter and it is unfortunate that so few manufacturers have given attention to it.

F. C. MOCK, Engineer,  
Stromberg Motor Devices Co.

## Distribution of the Automotive Vehicles in Surplus War Materials

THE Bureau of Public Roads of the U. S. Department of Agriculture has made the following statement of allotments and deliveries of trucks, Fords and other cars from surplus war materials to the several States, and retained by Department of Agriculture to June 1, 1921:

State	Total Vehicles Allotted	Trucks Delivered	Fords Delivered	Other Cars Delivered	Total Vehicles Delivered	Per Cent Delivered
Alabama	562	439	55	3	497	88
Arizona	366	277	22	3	302	88
Arkansas	450	389	40	1	430	95
California	816	601	75	14	690	85

# Overcoming Organized Labor Opposition by Fairness

The British coal strike has shown the difficulty of industrial adjustment where completely organized forces are opposed to each other. Similar development may occur here unless broad-minded, fair methods prevail among employers. A shop closed against union men is not an open shop.

By Harry Tipper

**T**HE reports of the end of the British coal strike indicate that for a time, at least, the question of nationalization of mines and the national pooling of wages is out of the way in that country. It would be a mistake to suppose, however, that the question is definitely shelved. The adherence of the main body of the miners to their leaders through the stress and difficulty of this strike is an indication of the solid character of the union organizations and the probability that the compromise accepted is accepted as an interim agreement only.

Meanwhile the strike in some of the other mines, difficulty with various portions of the textile trades and other agitations show the general tendency of the labor unions to continue their demands and to force the manufacturers into giving up more or requiring the public to pay more. Although there was no insistence among the leaders of the coal miners for a nationalizing of mines in this particular strike, the attempt to enforce a national pool for wages was so definitely in that direction that it must be considered a part of the same program.

The settlement indicates that the subsidies will be continued for three months in less amount, so that the people of Great Britain are paying for the settlement of this strike in the form of taxation for the support of the coal mining industry. These elements of the situation in Great Britain are of interest to us because they show the difficulty of adjustment and the tendency to industrial disruption in a completely organized industrial country where the forces of organization are opposed.

Despite the employment of the Whitley councils and the settlement of many minor strikes through this machinery, the difficulties of agreement between unions and employers' groups are not reduced by the complete development of both sides into organized groups frankly and definitely opposed in their ideas and methods of treatment. These things indicate also the tendency of strongly organized groups to continue their pressure upon government without respect to the economic conditions or the effect of their actions upon the economic development.

Considering the depressed state of trade in Great Britain, the number of people without employment, and the general hardship to be endured among many sections of the populace, one would be inclined to think that the pressure of demand would decrease and the groups would tend to come together for the time being in the common necessity for the reduction of costs and the enlarging of production.

When the organized forces reach practically their maximum of development with their programs of development thoroughly worked out, the momentum required in the course of this definition exerts a pressure on the leaders to continue their movement without regard to its present effect. To a much larger extent than we realize, the development of British commerce in the next few years and the political attitude to be taken in international questions depends upon the settlement of the political industrial program and the position of the labor party in regard to it.

Under the present conditions of the United States, we are likely to over-estimate the effect of the economic conditions upon the organized groups of workers and their development. The development of the open shop movement is a case in point. Where the open shop has been established and continued so that it is in advance of the trade union and is organized with the spirit and practice of square dealing, it offers good hope for the future. In many cases, however, the open shop is merely a means of escape from the union and a means of throwing the union out of the shop.

In discussing this matter with a friend of mine the other day, he informed me that he had come out for the open shop at the beginning of the year and was obliging all his workers to give up their union cards. "Why do you want them to give up their cards?" I asked. "Nobody can work in my shop and belong to a union," he said. "It's an open shop." This man really thought he was running an open shop, whereas he was just operating a shop closed to union men, and in so doing he was adopting the policy of the union, but turning it against the union.

Methods of this kind do not destroy the organization of workers. Men do not organize for insignificant reasons and they do not lightly reject their possibilities of organization. In times of distress they may subdue their desire or give up the idea entirely because of their fear of starvation. Unless they have confidence in the manufacturers and the management to give them a square deal, they will organize just as soon as there is any advantage in doing so, and they will organize more strongly as the necessity grows.

We do not want to reach a stage in this country representing the highly organized condition now existing in Great Britain. It would be unfortunate if we were obliged to adopt such clumsy and cumbersome machinery for the settlement of disputes. It would be a very great misfortune if we were to

arrive at the place where the organizations were so definitely opposed and equal in strength as to make settlement impossible.

Both these eventualities are possible in this country. If we succeed in diverting the industrial organization into other channels, it will be because of the intelligence, understanding and spirit of fairness among the manufacturers so that they manage their shops with equal justice to all concerned, whether they are members of unions or not, with some real understanding of the workingman's difficulties and ideas and with some comprehension of his fundamental necessities.

With those standards in view sufficient progress will be made in a few years to prevent the further development of separate organizations as the industrial prosperity grows. Unless intelligence of this kind is used, returning prosperity will show an increase in the number

of unions and in the membership of those unions, whether they be trade unions or unions of another character.

The leaders of the workers must come out from among the executives or from among their own ranks. They have leaders from among their own ranks who have been of value and visible usefulness to them. Temporarily they are not able to control the situation and are willing to accept what is necessary. This, then, should be used by the management of industry to show the workers there are leaders in industry capable of leading the whole establishment, including the workers, worthy of their confidence and trust, and more intelligently concerned with their future. This sort of leadership is the best guarantee against the conflict of trade union against manufacturers' group so painfully apparent in the difficulty experienced in Great Britain.

## Effect of Gasoline Quality on Engine Performance

WITH the present design of aviation engines and the means of vaporizing and distributing the fuel now available, commercial low test automobile gasoline does not give satisfactory performance. Detonation obtained with the compression ratios now in use precludes the use of straight, low test fuels unless anti-detonating compounds are mixed with the fuel. For this reason it would appear impractical to use commercial, low test automobile gasoline in present types of aviation engines, except in emergencies.

These conclusions are the result of experiments at McCook Field, which are interesting in view of the fuel situation, particularly as bringing out the fact that present-day gasoline is responsible for rather low engine efficiency. As is well known, the fuel ordinarily used in aviation engines normally has a much lower average boiling and end point than fuels commercially available for general automotive purposes. Distillation curves of the domestic aviation gasoline and commercial automobile gasoline are shown in Fig. 1. The domestic aviation gasoline is the fuel used in the army air service as standard for ordinary

flying, but is not composed of as low boiling fractions as those which go to make up the army air service fighting gasoline. The results of the comparative tests which were made on a standard, twelve-cylinder Liberty engine are clearly brought out in the accompanying curves plotted in Fig. 2.

In making the tests, a 5 hr. run with aviation gasoline was made, after which a similar run using the low test gasoline was attempted. This could not be completed until 6 per cent of anti-knock compound, consisting of Xylidine, was mixed with the fuel. The net results of the run are shown, as far as power is concerned, in the curves. After the torque stand runs were completed, an inspection of the pistons, cylinders and valves were made. The carbon deposit on the pistons was heavier than is usually obtained with domestic aviation gasoline. The most objectionable characteristics of the low test fuel is its pronounced tendency to detonate with compression ratios which do not cause detonation with ordinary aviation fuels. A notable increase in carbon deposit and in crankcase dilution was also found with the low test fuel.

Fig. 1 (Left)—Distillation curves of commercial automobile gasoline and two grades of gasoline used in aircraft engines. Fig. 2 (Right)—Power and fuel consumption curves, showing performance of Liberty twelve-cylinder aircraft engine using commercial automobile gasoline and domestic aviation gasoline. Results corrected to standard temperature and barometric pressure

## Selling Transportation

THE future of the truck lies in its record of performance as an economical transportation unit. Manufacturers must educate their dealers to sell transportation. Before they can do this the manufacturers themselves must study carefully the factors involved in transportation analysis. The more quickly this is done, the better will be truck progress.

Many of the trucks that have simply been sold as trucks are piling up transportation records unfavorable to the industry. At least they have not been performing as efficiently as if they had been sold after a careful analysis of specific transportation needs.

In a city of 100,000 population in New York, for instance, a recent survey of department store motor hauling showed some interesting facts. All of the six large department stores in the town had motorized their delivery to some extent. But in only one case out of the six had there been made any analysis of routing delays, loading problems, operating costs and the relation of such factors to one another.

The records being made by the trucks of the other

five stores would not show truck performance in its best light. It is to the advantage of the manufacturer to study the problem of selling transportation.

## A Factor in the Tax Situation

BUSINESS men recently have had placed before them some very startling lessons in economics. The railroads, for instance, have learned that it is possible to erect a rate barrier that will stop shipments of certain commodities. Many other lines have learned that it is quite possible to price an article at a figure that the public simply will not pay.

So it comes to general knowledge that there are other points to be considered in Federal taxes than the mere amount of the tax paid. Along with the popular demand for lowered Federal taxes comes a proposal for a bonus to be paid to the soldiers in the world war. The amount of this bonus will, of course, increase the amount necessary to raise in the form of taxes within the next few years. But there are other points to be considered, and these are well pointed out in a recent letter written by Secretary of the Treasury Mellon to Senator Frelinghuysen. Any transaction that amounts to well over \$1,000,000,000 is certain to have a very important economic bearing on many lines of business. This subject is well worth close study on the part of those interested in business in a big way.

## Effect of Racing Engines of Small Displacement

THE announcement in last week's AUTOMOTIVE INDUSTRIES that the 1923 Indianapolis race will be confined to cars fitted with two-litre (122 cu. in.) engines has been coupled with the suggestion that similar practice may be later reflected in the design of American cars, since it has already had a similar effect in Europe. We are inclined to doubt the probability of such an effect in this country for several reasons.

In the first place, an engine of this size is suitable for propelling only a very small and light car, a smaller car, in fact, than has ever proved popular in this country. Most of the European cars with engines of this size are in reality diminutive automobiles, many of them with narrow track and small passenger-carrying capacity. Even then frequent gear changing is necessary. It is, furthermore, a difficult and expensive job to build a light car that will stand up on any but the best of roads. By light car we mean a car comparable to the cars with engines of 100 to 125 cu. in. displacement, or thereabout, such as are now quite popular in England.

In the second place, the use of so small an engine involves relatively high engine speed and large gear reductions in order to give the car the requisite ability and road speed, and to build a successful high-speed engine requires a much higher grade of workmanship and much more care in balancing, as well as lighter and more expensive materials, than it is possible to employ in large quantity production of cars designed to sell at a low price. To be really successful a car

of the class referred to must be capable of meeting the competition of the larger and more rugged car produced in quantity at a lower price. The fact that the car is economical in tires and fuel will not offset a much higher first cost, especially if, as is often the case, servicing is more expensive.

In the third place, there is reason to question the claim sometimes made for the efficiency of small high-speed engines as compared to the larger and slower speed types of engine. It is probable that the friction losses are greater, relatively, in the higher speed type. It seems probable also that by a proper selection of gears in the final drive, the larger and slower speed type can be made to operate under more favorable load conditions, and consequently at higher efficiency than the higher speed job. In any case it does not necessarily follow that, because the engine is small and capable of a high rotative speed, it is relatively more efficient.

Members of the Bureau of Standards staff, in a paper read at the recent S. A. E. meeting, presented some data tending to show that larger and slower speed engines are more efficient than the higher speed type, even when the difference in weight of engine and car, in favor of the latter type, is taken into consideration. There is need for further experimental evidence along this line, however, for there is no doubt concerning the desirability of more economical cars, due regard being given, of course, to first cost as well as to operating cost.

## Understanding Sales Prospects

**T**HERE has been considerable discussion recently concerning territorial analysis and more accurate determination of future sales possibilities. The purpose of such studies has been, not only to stabilize production, but also to permit the establishment of fairly accurate quotas by which to measure dealer performance. The effect of such efforts on the dealer should be considered. An incident recently occurred which illustrates the good effects of such studies on both dealer and manufacturer.

This manufacturer has done extensive work in commercial research and merchandising analysis. On the basis of these studies he has re-established dealer territory boundaries along scientific lines. The process of readjustment is still under way.

The other day one of the big dealers made application for more territory. He claimed that people from a certain near-by town were coming to him for cars, and that he could not sell them because they were in another dealer's territory. The other dealer, he claimed, was not adequately handling the business.

We happened to be present when this big dealer was discussing with a factory executive the matter of increasing this territory. It was refreshing to listen to the line taken by the conversation. The talk was a discussion; not an argument. The dealer was forced to outline his side of the case in concrete terms on the basis of accurate merchandising facts. He knew that the factory executive had made a careful merchandising analysis of the territories involved; that the factors of population, property values, regis-

trations, incomes, etc., had all been considered. To present his case the dealer had to understand thoroughly all these factors concerning his own territory, to begin with. He had to study carefully the sales possibilities of his own and the adjoining territory and to arrange the results of that study in logical sequence.

We don't know whether or not the dealer got the extension of territory. But it is certain that if he did not get it, he knew that it was refused on the basis of sound sales facts.

When it is possible to discuss such matters on an intelligent basis, good feeling and co-operation are enhanced, and each party to the discussion knows that he has won or lost on a fair and honest examination of fundamental facts. Merchandising studies are beneficial to both dealer and manufacturer. In this case, for instance, whether the dealer got the additional territory or not, he had dug up and understood many valuable facts about his own territory which will be of advantage in future selling.

## What Mr. Babson's Figures Told

**D**URING the recently somewhat gloomy months there was much attention given to the figures of Roger W. Babson. These figures added fog to the gloom. There were a few hardy men who dared to say that they did not believe all that Mr. Babson said of the future. Recently these men may have been fooled into the belief that they were right and Mr. Babson was wrong, but not so. Mr. Babson now comes forward with the true story of what his figures have revealed in the future. He is quoted as follows in a Chicago dispatch to a New York paper:

Automobiles built of a composition of cotton and operated with coal dust for fuel are a possibility, according to Roger W. Babson, statistician, who is visiting here.

"The principal factor in the decline of the automobile business has been the increase in the price of gasoline," he said. "The car of the future will be run by other fuel. Already the use of coal dust has passed the experimental stage.

"Lighter cars must be manufactured to cut down the cost of production and maintenance. A composition of cotton, formaldehyde and glue is being used to produce a material that may solve the problem."

It is possible that Mr. Babson, like Admiral Sims, may say that the thought is more of the newspaper's reporters than his own, but we hope not. It is so clear and concise a solution of the problems of the automotive industry that we hope he will stand by it and prove it with more figures.

When this solution is proven, the industry's only concern will be as to whether the coal miners are going to strike and how much cotton the planters will plant, and how high the speculators and middlemen will force the prices of the two essential commodities. Of course there will be the railroad problem, but we have that now. How much easier of solution are these two problems than the present one of wondering how much oil there is in the earth and how well the oil refiners are going to prepare it for the engine.

# Business Puts Pessimism to Rout

## Trade's Evils Less Than Omens of Good

### Outlook Points to Certain Revival As Favorable Signs Loom on Horizon

By James C. Dalton

NEW YORK, July 11—There are two outstanding facts about the status of automotive industry as the middle of July approaches:

Business is considerably better than many persons within the industry think it is.

Business is very much better than people in general outside the industry think it is.

Governor Harding recently told the members of the National Automobile Chamber of Commerce that the worst thing about a pessimist was that he usually was pessimistic at the wrong time.

The impression seems to be almost universal among those who have not followed the situation carefully that the automobile trade is suffering from a bad case of the doldrums. The Guaranty Trust Co., for example, the second biggest bank in the United States, in its survey of general conditions for June, has this to say:

"A decline in the demand for automobiles, accompanied by numerous recessions in prices, is reported. The slackening of demand is affecting both truck and passenger car output. About one-third of the companies actively engaged in the production of passenger automobiles in the United States have revised prices downward since April. The recessions in prices have been proportionately larger for the lower-priced cars than for those selling at higher prices.

"A reduction in the demand for automobile tires, corresponding in a measure to the lessened demand for automobiles, has affected the activity of a number of rubber companies. In accordance with curtailment of production schedules, workmen have been laid off.

"Earlier in the year there was a considerable increase of business in the automobile and tire industries, an increase which resulted in exaggerated expectations concerning the immediate future of these industries."

#### Summary Far from Facts

This summary could not have been much further from the actual facts in relation to June. There was a falling off in sales at retail the latter half of May, but it was not reflected in the factories. Sales in June were larger than for any month of the year thus far, and

it was one of the largest Junes in history. There has been no reduction in demand for tires and all the large factories increased their production schedules last month.

"Earlier in the year" there may have been some "exaggerated expectations" concerning the future, but they were not shared by well informed men in the industry. On the contrary, actual conditions as they have developed warranted greater optimism than was felt in most quarters.

It undoubtedly is true that there would have been a sharp slump in sales if prices had not been cut. They were cut, however, and a flood of orders followed.

While it is certain there would have been a slump in sales if prices had not been reduced, it is equally certain that there will be a slump unless prices are stabilized in the very near future. No person to whom money is an object is going to buy an automobile unless he has some assurance that he can't get it \$150 or \$200 cheaper a month from now.

#### Reasons for Reductions

Two well known companies in the same class have cut their prices twice in a month. The first company to reduce felt an immediate stimulus in its business. The sales of the second stopped. Then the second company cut, but still sales didn't start, and it made a second cut. Then the sales of the first company slowed up and it made a second cut.

There were many reasons why automobile prices should have been cut, but there is every reason in the world why they should not be cut every two weeks. Such a price war would be ruinous. It would do more than anything else possibly could to check sales. When a man buys even a pair of shoes and then finds that he could have bought them \$1 or \$2 cheaper a week later, he instinctively feels that someone has made a fool of him, and this engenders a certain amount of animosity toward the maker.

#### Signs Point to Business

Dog days usually are dull in a business way, but this year they will afford the tired business man and manufacturer an excellent opportunity to scan the industrial horizon and figure out intelligently what's going to happen two or three months from now.

The signs are on the horizon now and it doesn't require superhuman intelligence to read them. The favorable omens greatly outnumber the portents of evil. The fundamentals upon which business and trade rest are stronger than they have been in eighteen months. They point to a gradual but none the less certain business revival in September or October at latest.

There was foolish optimism a year ago and there is needless pessimism now.

## Detroit District's June Output 169,041

### Steady Upward Trend in Demand Shown by Increased Production at Plants

DETROIT, July 11—Evidence of a steady upward trend in automobile demand, influenced in great measure by price cuts, is shown by increased production for June in Michigan factories. The output aggregated 169,041, an increase of 24,440 compared with May. Production of 108,962 by Ford against Ford output of 101,897 in May is responsible for a third of the increase, but there was a step-up in nearly all factories, particularly Dodge and Buick. Increase in output of Hudson-Essex, Maxwell, Paige, Packard, Studebaker, Chevrolet, Hupp and Olds also were marked, and slight improvement was shown in practically every factory in the district.

Dodge, which built around 450 a day the greater part of June, swung into capacity production during the latter days of the month, and official announcement is made that an average of 600 cars will be run off assembly line daily for the balance of the year. Olds Motor Works turned out 3100 in June against 7175 in May.

Packard went up about 200 in the month, Hudson about 100, Essex about 200, Paige 400, Hupp 250, Chevrolet about 1500, Studebaker about 1000 and Maxwell more than 1600. Buick went more than 6000 ahead of May.

#### Working on Full Time

Packard, which built 1000 cars and 180 trucks in June, is working full time with slightly less than 50 per cent of the peak force, but officials say if present demand continues, a step-up in production will be imperative. Oldsmobile officials report steadily increasing business and prospects for an exceptionally big demand in July.

General Sales Manager Hutchinson of Hupp Motor Car Corp., said the factory had orders on the books for more cars for July delivery than were turned out in June, with daily demand showing a decided upward trend. The same is true of Paige, at which plant the June production was 400 greater than May.

President McAneeny of Essex Motors said Hudson and Essex factories were turning out 140 cars daily at the present time and would continue that production indefinitely, the output being based strictly on sales requirements, which for the last four weeks have been climbing steadily.

# Set \$40,000 Sales Promotion Fund

## Jobbers Make Plans to Stir Up Buying

Section by Section Development Likely Under Specially Engaged Promotion Director

MACKINAC ISLAND, MICH., July 11—A sales promotion campaign intended to broaden the outlet for products of the automotive equipment industry by educating jobbers, jobber salesmen and dealers in improved merchandising methods was authorized by the Automotive Equipment Association, which adjourned its summer convention here to-day.

The association appropriated \$40,000 for the undertaking, \$15,000 of which will come from the treasury and the balance from assessments on members, including both manufacturers and jobbers. A permanent committee was appointed to map out the campaign and to employ a sales promotion director and assistants to do the actual work.

On the sales promotion committee, which is to be permanent, were appointed Robert A. Stranahan, president of the association and president of the Champion Spark Plug Co., Toledo; N. H. Oliver, Metal Specialties Co., Chicago; L. R. Safford, McQuay-Norris Mfg. Co., St. Louis; Howard M. Dine, vice-president of the association and head of the Dine-De Wees Co., Canton, Ohio; W. W. Lowe, Electric Appliance Co., Chicago. The first three are manufacturers, the remaining two jobbers. The committee expects to meet in Chicago in the near future and get under way the plans for the new work.

### Campaign in Sections

The sales promotion probably will be developed section by section throughout the country with the director and his assistants personally presenting the idea to groups of jobbers and their salesmen, and the latter carrying it on to their trade. Presumably there will also be literature supporting the personal work of the staff.

The sales promotion idea met with the unanimous approval both of manufacturers and jobbers, who realized that sales of automotive equipment and consequently factory production were limited by lack of aggressive and intelligent merchandising in many dealer establishments. The jobbers frankly confessed also that they would like to have the educational work applied to their own selling organizations. They believed that the right sort of effort would not only make better merchants of dealers and garagemen already handling accessories but through exposition of the opportunity for profit would induce others in auto-

## SCRIPTURAL SIGNS NEW DANGER MARKS

UNIONTOWN, PA., July 11—Instead of the usual danger signals at points in the mountains that require careful driving of motor cars, there now have been placed scriptural warnings. No one seems to know their source. The signs are wooden ones, 3 feet by 2. At the most dangerous curves on the national pike between here and Cumberland are warnings, "Prepare to Meet Thy God," and similar cheerful quotations from the Bible that have an appropriate bearing.

motive merchandising and service lines to take up equipment selling.

The membership showed so much enthusiasm over the sales promotion plan that an additional \$25,000 for the coming year was unofficially promised.

In connection with the proposed sales promotion work, the association went on record favoring payment by retailers of commissions on accessory sales over and above the regular salaries of employees making them.

It was tentatively decided to establish a permanent traffic bureau for the association with a full time staff. A traffic man is now giving part of his time to the work at Chicago headquarters and has already saved members considerable in trade overcharges. The bureau probably will be established at the annual meeting in November.

A code of fair trade practices, for the guidance of both manufacturers and jobbers, was adopted with 35 clauses.

The meeting was attended by delegates representing 133 manufacturers and 99 jobbers.

## 13,759 Buick Owners Receive Cars in June

DETROIT, July 11.—Buick Motor Co. delivered 13,759 cars into the hands of owners in June. Shipments last month were 3800 more than those of the entire first quarter and represented actual retail sales at the rate of 530 cars daily compared with peak plant capacity of 600 cars a day.

E. T. Strong, general sales manager, said that Buick figures for June disprove the assertions that the automotive industry is through with big figures. "They are evidence that the industry has earned the right to the title of one of America's greatest industries," he said, "and that the spirit of pessimism prevalent in some quarters did not faithfully represent the sentiment of the public.

## Steel and Wage Cuts Bring Cheaper Cars

Cleveland Manufacturers Declare Some Did Not Get in on Low Prices

CLEVELAND, July 11—Cleveland automobile manufacturers as a rule say that it is too early yet to prophesy what results will follow the cut in prices of steel recently made by the United States Steel Corporation.

Some of the producers say they have been buying at the new market price of steel for the past two or three months, and that the public announcements of price reductions are but confirmation of prices of which they have had the benefit.

Manufacturers who buy their bodies expect a reduction in costs as do others who purchase parts and assemble cars. These manufacturers are getting in touch with concerns from which they buy, in an endeavor to ascertain just where they will stand in the near future in the matter of prices for parts.

### Some Not So Lucky

Still another class of manufacturers has not been obtaining steel at the new prices. They say the result should lower costs as they have been purchasing above the new price levels.

One manufacturer pointed out that there is evidently some rivalry between the independents and the United States Steel Corp. The independents some months ago were quoting higher prices than the corporation, and as a result the plants of the latter were kept running with a larger output than were those of the former. Then the independents cut to a point below the corporation and now the latter has gone below the independents. The steel situation is likely to bring developments even more beneficial.

The cut in steel prices, coupled with a general reduction in wages of approximately 15 per cent in all local automobile plants since the first of the year, together with price reductions have tended to get the industry back to normal.

It was developed that local manufacturers who convert steel into their machines have been buying closely, and have been playing for price reductions, while practically all have been asking for the benefit of price reductions on material delivered on contracts made before the lowering of values. This is relied on to keep inventories down to near where they should be.

The Stearns Co. has made more cars this year than it did in the same period a year ago. The store room is empty

## Highway Prospects Brighter in Mexico

### American Delegates Return With Optimism After Conference With President Obregon

SAN ANTONIO, TEXAS, July 11—Prospects are bright for the improvement of the proposed Mexican highway from Laredo, Texas, to Mexico City, the capital of the southern republic, as an international extension of the Meridian Highway across the United States. This optimism was brought to San Antonio by delegates of the Meridian association, who have just returned here after a promotion trip along the proposed route. Conferences with local and State officials were held at each of the larger Mexican cities, and at Mexico City the delegates were in conference with President Obregon and Señor Faustino Roel, present head of the Mexican Department of Communications and Public Works.

"We found the people of Mexico overcoming their difficulties with a smile," D. E. Colp, vice-president of the Meridian association and manager of the truck department of the Nash South Texas Motors Co. here, declared. "The country is fast returning to normal. The Government has five big road projects under construction and it expects to keep building until the Republic has a good system of highways. The Mexicans realize what the tourist business means to any country and they are correct in assuming this will be large if proper highways are built. President Obregon discussed the highway problem at length with us and told us that the Government was caring for many of its people by giving them work on the highways.

"All the road work in Mexico is being done by hand, no machinery being used. Nevertheless, the work is fine and costs only about one-fourth what it would in this country. The roads are being built 20 ft. in width, to carry all kinds of traffic."

#### Hold Official Conference

Conferences with the State governors, chambers of commerce and local business men were held at Monterey, Saltillo, San Luis Potosi, Queretaro and Mexico City. Agricultural organizations likewise were represented at the conference, and provisional officers of the Meridian Highway Association were elected after each conference. At Monterey, Señor Carlos Cantu was named president; Señor Antonio Lopez at Saltillo; E. B. Turnbull at San Luis Potosi, and Señor Lorenzo de Vicento at Queretaro.

At Mexico City, it was decided that a general conference of all the highway committees of the several states would be called within a few months, probably in September. Then, the Mexican organization could be so perfected that the active work of locating and improving the highway might be gotten under way.

The delegates were taken from Mexico

City by automobile to Cuernavaca, in the State of Morales, over a recently completed highway some 45 miles in length. The State of Morales is famous for the revolutionary activities some years ago of Emiliano Zapata. The visitors, however, found conditions so peaceful that the hotels at Cuernavaca did not even have keys for their doors.

"Everywhere new business activities were manifested," a report of the trip declares. "Commercial enterprises were being reconstructed and a general feeling of peace and prosperity prevailed everywhere."

The delegation included all members of the Texas State Highway Commission, with officials representing the Meridian association, State organizations of Texas, Oklahoma, Kansas, Nebraska and the Dakotas. Accompanying Mr. Colp were G. A. MacNaughton, treasurer of the association, of San Marcos, Texas.

Letters and a committee also have been received by the association asking that a similar tour be arranged over an eastern route from Brownsville, Texas, through Tampico to the Mexican capital. Mr. Colp hopes to organize such a tour.

### Daimler Firm Settles Dispute; Work to Resume

LONDON, June 22 (By Mail).—An official announcement was made last night in Coventry to the effect that the Daimler company's employees had decided to accept the company's proposed terms and that it is anticipated that production will be resumed very shortly.

The trouble which has resulted in the Daimler plant being practically closed down for several weeks arose from the fact that the Engineering Trades Union held out in refusing to allow the company's employees to accept the revised terms of payment which the majority of the staff had in a ballot voted in favor of accepting. The dispute has, therefore, not been between the company and its employees, but between the latter and their union officials. One of the latter in a statement last night said: "We have arrived at some arrangement with regard to future prices for work, and if the Daimler company have work the men will be employed, but we do not anticipate any large amount of employment in the near future." This rather indicates the truth of what has been suspected, namely, that the company has not been very concerned at the stoppage, owing to the fact that the falling off of sales would not have enabled them to keep in full swing at any event.

#### URGES FRENCH AIRPLANE FLEET

PARIS, June 21 (By Mail).—Deputy Paul Benazet has introduced a bill into the French Chamber of Deputies which proposes to establish a fleet of 1000 airplanes suitable for war, but which can be operated commercially and therefore at little cost to the Government. The author of the measure called attention to the large and extensive aviation personnel of the Government.

## Spring Business Fair in Dominion

### U. S. Consul, Reviewing Outlook, Says Improved Sales Assure Better Business

WASHINGTON, July 12—Pointing out that there has been a fair spring business for automobiles in the Canadian market, Consul Felix S. S. Johnson, Kingston, Canada, prepared a report with regard to the present outlook for the sale of automobiles in that country.

"Discussion of the automobile market is connected frequently with the buying power of the farmers," it is stated, "and in view of the heavy reductions of the prices received by farmers for their products it has been thought that the automobile market would naturally be curtailed. Prices are not yet back to the 1914 level, and that is not expected, unless the industry is prepared to suffer crippling losses. Reviewing the outlook for the automobile sales, it can be said that while it is proved the recent price reductions have been made to meet competition, it is equally true that this should have the effect of bringing the price of cars down to the reduced buying power of the country, which has naturally decreased very sharply during the last six to nine months.

"The industry has plainly entered the competitive area for the first time in its last three years. It is going to be a struggle to get business and the race is likely to go to the strongest. During the abnormal demand of 1919 and 1920 the automobile producing capacity of the country was vastly expanded both by additions to plants by old companies and through formation of many new companies. Some of the new companies are making their bow to the buying public at a time when competition may go to the length of forcing weak or high cost companies to do business at a loss. In fact, broadly speaking, the May price cuts have probably eliminated the great bulk of profit which was still left in the industry. These price cuts were not based on a scientific revision in accordance with lower steel, lumber, leather and parts. They were purely competitive and were designed to get business in a greatly curtailed selling market."

#### OPEN TRACTOR DEMONSTRATION

FARMINGDALE, L. I., July 12—A demonstration of farm power operating machinery was started to-day in this town by the Farm Implement and Farm Power Machinery Development Association, co-operating with the State Institute of Applied Agriculture. The demonstration will include plowing, cultivating, planting, harrowing, threshing, wood sawing, hauling and road grading. There will be about 25 tractors in operation varying in size from 1½ up to 45 hp. Several farmlight plants and water systems as well as a number of stationary engines will also be exhibited.

## Rubber Plants Near Peak of Production

75,000 Tires Manufactured Daily at Akron As Normal Business Looms

AKRON, OHIO, July 11—A survey of the rubber industry in Akron shows that practically all companies have climbed back to a position averaging 75 per cent of peak production attained in April, 1920. Over 75,000 tires are being manufactured daily in the rubber metropolis and all companies report orders on their books, both from dealers and automobile manufacturers, to keep their factories running at present pace through July and August and possibly September.

Dealers' sales of tires are heavier than they were a year ago, tire manufacturers assert, while automobile manufacturers have sent in heavy original equipment tire specifications for July and August, and also have given notice that they anticipate equally as heavy orders in September.

Goodyear, the largest and the hardest hit of the Akron tire companies during the industrial depression, has been one of the first to stage a spectacular "come-back." Having liquidated its losses through refinancing involving \$88,000,000, and through re-organization of the entire company, Goodyear has experienced a steady climb back to a position closely approaching normal, and with the addition of 3000 men during the past two weeks, now is operating on a basis of 86 per cent of peak production.

Goodyear's peak was 31,181 tires daily, obtained in April, 1920. To-day the Goodyear factories in Akron and Los Angeles are making a total of 26,700 casings daily and 30,500 tubes. The Akron factories are operating on a production ticket of 23,200 casings and 27,000 tubes daily, and are running on a basis of three eight-hour shifts daily, and six full days of operation a week, with approximately 11,000 men employed. The company reports dealers' sales steadily climbing, and far in excess of dealers' sales for the corresponding weeks of last year, and also reports that automobile manufacturers have placed heavy July and August orders for original equipment.

That the Goodyear factories will continue to operate on the present basis, and may possibly increase production within the next two months, is freely predicted by officials of the company.

### How Business Increases

The Firestone Tire & Rubber Co. is operating on a basis of more than 70 per cent of peak production which was 28,000 tires a day, attained in April, 1920. Firestone has lengthened its two daily shifts to nine hours each and is operating on a production basis of 20,000 casings and 23,000 tubes daily.

The B. F. Goodrich Co. has not materially increased production within the

## COSTS JAPANESE \$10 TO OWN CAR ALL YEAR

PONTIAC, MICH., July 11—Two hundred Japanese are riding in one Oakland touring car which they each call their own, through a co-operative idea established by a Japanese company. The firm was organized with an initial capital of \$150,000 and the first purchase was 55 Oakland touring cars. These have been sold to 11,000 Japanese under the plan by which the company operates.

Each stockholder pays \$10 and in return receives a one year's interest in an Oakland touring car. The year has been divided into days and hours and a specific time allotted for each stock holder to take a ride. For instance, a man is notified that his time will be from, say, every Thursday from 11 o'clock to 3. The arrangement nets the firm \$2,000 for each car sold and gives the Jap automobile enthusiasts the satisfaction of being a car owner for the very modest investment of \$10.

past few weeks, continuing on a basis of about 15,000 casings and 16,000 tubes daily.

### About Labor Turnover

Every Akron tire company reports a much higher degree of efficiency among factory operatives than a year ago when abnormal wages were paid tire builders and when Akron was in the throes of prosperity and wanton extravagance. Whereas the factories previously averaged about a tire a man per day, they are now showing more than a tire and a half per man in many departments, while the general average of increased efficiency, as reflected in production records, will exceed 40 per cent. Workmanship is better, factory managers report, and in re-employing men a higher grade of workmanship has been gained in general.

Labor turnover to-day is almost nil in Akron. A year ago when jobs were plentiful, when several Akron factories enforced a \$6 daily minimum factory wage, and when every rubber company was calling for men, the labor turnover in some instances reached a mark in excess of 30 per cent. But to-day, manufacturers state, conditions are in sharp contrast, and labor turnover has been reduced until it has become negligible, through each factory operative's desire to hold onto his job as long as possible. The weeding process also employed in practically all factories, has conducted greater individual and collective efficiency. Rubber companies which have put on men in blocks of several hundred or a thousand, have picked them carefully from the many applicants, and at the same time have used many of them to replace careless workmen.

## Four Duesenbergs in Grand Prix Race

U. S. Will Be Represented for First Time in Fourteen Years in French Classic

INDIANAPOLIS, July 11—American interest in the French Grand Prix which will be run at Le Mans July 25 will be centered in the four Duesenberg cars which will face the starter. It is the first time in 14 years that an American entry has appeared in the European racing classic.

The Duesenberg entries have not been made by the company which manufactures the car but rather by Americans interested in racing who believe that the American machines can carry off the honors. The funds necessary to send the four Duesenbergs abroad were subscribed by Richard Kennerdell, chairman of the contest board of the American Automobile Association; Albert Champion, president of the Old Timers' Club; Barney Oldfield and others.

The drivers who will pilot the cars in the Grand Prix are thoroughly familiar with them and have previously driven them in races. Joe Boyer and his mechanic Erne Olson sailed for France early last month and Jimmie Murphy two weeks later. The other pilots will be Guyot and Inghibert, French veterans who are taking the Duesenberg against the best racing car drivers of Europe.

Among the cars and drivers entered are: Ballot, De Palma; Sunbeam, Rene Thomas; Talbot, Dario Resta; Ballot, Chassagne, and Sunbeam, Boillet.

The Grand Prix this year will be the first since 1914 because of the war and the first at Le Mans since 1906. It is a road race of 321 miles, 10 miles to a circuit over level dirt roads with many dangerous turns.

All the Ballot cars will be equipped with Goodyear tires.

## Fiat Car Not to Start in Grand Prix Races

PARIS, June 29 (By Mail).—Fiat will not start in the French Grand Prix race at Le Mans on July 25. This decision has been taken by the leading Italian firm after having paid entry fees amounting to \$7100, but without any explanation being given as to the reason for the withdrawal. The Grand Prix cars have been on the road for some time and new eight cylinder engines have been built and tested, it is declared, with good results.

### TOOL FIRM GOING TO POLAND

ROCHESTER, N. Y., July 11.—Stockholders of the Rochester Auto & Tool Co., a \$75,000 corporation here, owned principally by residents of Polish descent, have voted to remove the equipment of the plant to Jaslo, Poland. The plant has been in existence two years.

## U. S. Gives Goodyear Aircraft Contract

### Akron Plant Will Be Busy One Year Making Balloons and Dirigibles

AKRON, O., July 11—Regardless of the outcome of the present spirited controversy now current in congressional circles as to the comparative advantage of aircraft and heavily armored battle-ships as America's first line of defense, both the army and navy are to have more lighter-than-air ships, orders for three large dirigibles and 38 observation balloons having just been placed by the Government with the Goodyear Tire & Rubber Co. of Akron.

The Government orders just received will keep the Goodyear aeronautical factory, which is the largest in America, busy for the next year, officials state.

Two patrol and scouting airships of 180,000 cu. ft. gas capacity each, will be built for the navy and will be delivered early next spring. A dirigible of similar size but of a special Goodyear design, will be completed for the army in November. All three ships will be officially tested at the Goodyear-Akron air station at Wingfoot Lake.

The military airship for the army will embody many new features of design which will make it the most modern aircraft in either arm of the Government service. It will be the first dirigible in American to have its motors in the car instead of in separate power units. Two propellers will be driven by bevel gears at a two-to-one ratio with transmission placed on outriggers instead of the motors driving direct to the shaft. This will allow the engine to run while the propellers are idle by throwing out the clutches, and will permit the propellers to be reversed—a new feature to permit greater facility in landing. Either motor can drive both propellers in the event one motor develops trouble. With both motors inboard they can be overhauled in flight much easier than on the outriggers, as in the present type of dirigible.

The army ship will be 170 ft. long and 45 ft. in diameter. It will be powered by two 125 hp. Aeromarine motors operating at 1600 r.p.m. Owing to the special reduction gear the propellers can be held down to 800 r.p.m., giving greater efficiency at higher speeds. The ship will have a speed of 60 m.p.h. and a "ceiling" of 10,000 ft. The car will be entirely enclosed and will house a crew of six, although three men can operate the ship in peace-time. The ship will be used for border patrol. The navy ships will be used for scouting.

### \$826 MELBOURNE CYCLE PRICE

WASHINGTON, July 12.—The average price of a motor cycle in Melbourne, Australia, is \$826, according to advice received by the Bureau of Foreign and Domestic Commerce. In 1911 it was \$315, and in 1914, \$365.

## TRACTORS MAY TAKE PLACE OF CITY MULES

INDIANAPOLIS, July 11.—The small tractor is assuming a new role in this city. The use of tractors is believed to be one method of getting the city out of a serious predicament. At the present time the board of sanitary engineers uses mules and horses in the ash and garbage collection departments. In casting about for a place to house all the animals the board found a suitable location in West Indianapolis, a part of the corporate city. Citizens of that section have protested to the point of beginning legal proceedings to dis-annex the entire section from the city, thus forestalling any municipal barns in the section. As a result the board is conducting a series of experiments with small tractors, which if successful probably will mean the elimination of every horse and mule from the department. Officials of the sanitary commission say the experiments so far have been satisfactory and it is likely that within 90 days the entire department will be motorized.

## U. S. Trade Board Cites Rubber Firm to Court

WASHINGTON, July 11.—Upon application for the issuance of a complaint the Federal Trade Commission has cited the Diamond Holfast Rubber Co. of Atlanta, Ga., in complaint of unfair competition in the manufacture and sale of automobile accessories and repair materials in interstate commerce. It is alleged that this company marketed its products in such a way as to pass them off as those of the Diamond Rubber Co., a subsidiary of the Goodrich company.

Further allegations are made that the respondent has marketed its products in containers with labels which feature the word "Diamond" and so closely resemble the labels of its competitor, the Diamond Rubber Co., in typographical arrangement, color scheme and general appearance as to cause confusion in trade. Thirty days are allowed for the filing of an answer after which time the case comes for trial on its merits, Aug. 9.

The Federal Trade Commission dismissed its complaint of unfair competition against the Super Tread Tire Co., South Bend, Ind., for failure of proof. The complaint alleged that the respondent circulated advertisements imputing that its rebuilt tires were new.

### RECORD SHIPMENTS FOR JORDAN

CLEVELAND, July 11.—In June the Jordan Motor Car Co. of Cleveland produced and shipped over 200 cars more than in any month in their history. May also was a peak month showing a 26 per cent production gain.

## Tire Firms Cut Down Fabric Obligations

### Goodyear and Firestone Progress Rapidly in Liquidations—Ease Contract Burdens

AKRON, July 12.—Considerable progress is being made by the larger tire companies in liquidating contracts for fabric which have been hanging fire for several months. Goodyear, which had contracts for 60,000,000 yd. of fabric, has taken delivery of approximately 10 per cent. Firestone is rapidly reducing its commitments and recently was compelled to refuse orders for certain grades of tires because they could not obtain sufficient fabric in time. Goodrich is taking delivery more slowly than the other large companies and does not expect to liquidate present contracts before 1922.

Various expedients have been adopted by tire companies to ease the burden of high priced fabric contracts inasmuch as there have been no cancellations. In some cases deliveries have been taken for from 25 per cent to 50 per cent of the contract at the original quotation and the remainder at the market price. Other companies are taking goods at the market price to be paid for on the usual terms and are giving long term notes on the difference due on high priced contracts. Some companies are understood to be buying cheap fabric in the open market to average costs.

Smaller tire companies which did not have large commitments either for crude rubber or fabric because they lacked the financial resources of the larger factories are in a much better position in regard to supplies and are taking advantage of the low prices on both these materials.

## Injunction Halts Use of Overland for Tires

TOLEDO, July 11 — Willys-Overland Co. has been granted an injunction against the Akron-Overland Tire Co. restraining it from the use of the name Overland in its corporate title or in any use in connection with its product. The order was handed down in the United States Circuit Court of Appeals in Philadelphia.

The injunction is interpreted to give in effect to the creator of a trade name in an industry the sole right to use that trade name in connection with any article which is commonly accepted as an accessory to the product which originally bore the trade name.

### PLAN RUBBER PRICE CONTROL

NEW YORK, July 12—A dispatch from London says the British Rubber Growers' Association has passed a resolution recommending producers to take immediate steps to reduce by 50 per cent the output of the association's membership. It is preparing a scheme for creating a selling organization with a view to control of prices.

## President Assures Tax Law Revisions

### Harding Allays Business Apprehension by Summoning Senate and House Leaders

WASHINGTON, July 11—Because of the apprehension existing among business men, President Harding has given assurances that the internal tax laws will be revised. Reports have been current for some time that Congress would continue its dilatory tactics until it would be necessary to reenact the tax laws without substantial change. Apparently, business men and industrial leaders had good grounds for this supposition. The President, however, knew that American business men would rise in righteous wrath in event the Administration's program for tax revision was side-tracked by the legislative branch of the Government. He is cognizant of the fact that many firms will be forced to the wall before the end of the calendar year, unless the inequities of the existing law can be removed. The Chief Executive has given serious consideration to the tax problem and, as a consequence, summoned Senate and House leaders for conferences as to the most expeditious way out of the difficulty.

The Senate has made one or two efforts to recess for the summer because of climatic conditions in Washington. At least, the climate is given as the excuse for a holiday, but the real reason is quite obvious—Congressional elections are scheduled for next fall and it is necessary to put their political machines into operation at an early date. The debate on the tariff bill closes July 21 in the House and then the House Committee on Ways and Means will take up the consideration of the revenue bill, for this measure must, under the law, originate in this committee. It is doubtful if there is one man in Congress who could safely predict the revision which the Senate and House will make in the tax laws. The Senate Committee on Finance will study the permanent tariff bill as passed by the House. It will not be held up in this committee because they have very definite ideas as to what they want in tariff legislation. It is quite certain that this committee will make many drastic changes in the House bill. The President has told the Congress to pass the tariff bill and revise the internal revenue laws without delay. He has suggested that lesser legislation should be pigeon-holed until the regular session.

### Harding Wastes No Time

It now appears that the Administration has put the quietus on the plans of Congress for bonus legislation. The President wasted no time in making known his desires on the subject. He took the bit in his teeth, so to speak, and called personally at the Capitol for conferences with legislative leaders. He told them very quietly but firmly that

the proposed enactment of the soldiers' compensation bill would be a rash move at this time and something which the Administration could not countenance in justice to the American taxpayer. Secretary of the Treasury Mellon stressed the fact that the bonus will cost the country \$2,200,000,000 in addition to the four or five billion which is required annually to conduct the ordinary process of government. The program of economy in governmental expenditures, which the present Administration adopted and has given admirable proof of its intentions to carry out, would have been shattered. One of the encouraging features of the situation is the fact that the bonus bill is not strictly a party matter, for Democrats, as well as Republicans, agree with the President that bonus legislation should be postponed.

### Chamber Opposes Bonus

The Chamber of Commerce of the United States is opposed to a bonus at this time. They state that the minimum amount that would be paid out by the Government under the proposed bonus bill exceeds the total annual cost of government for the fiscal years of 1915 and 1916. Secretary Mellon has said "I should be derelict in my duty to the country and to the veterans if I failed to give this warning of the inevitable financial consequences of the bill. This is not a time to impose several billion dollars of new liabilities on an already over-burdened treasury. It seems particularly inappropriate to give present consideration to the measure when we still have before us the pressing problem of revising the internal tax laws and finding sufficient revenue to meet the existing requirements of the Government. It would involve grave dangers of renewed inflation, increased commodity prices and unsettled business conditions."

## Survey Shows Slight Drop in Employment

WASHINGTON, July 12.—Analysis of employment conditions after an industrial survey by the Federal Employment Service, shows a slight decrease in the number of workers employed in the automobile industry during June.

According to the Federal Employment Service "detailed examination of the present returns indicates clearly the fundamental causes of the protracted industrial depression and the mounting tide of unemployment.

"Continued unsatisfactory conditions of transportation," it says, "with freight rates in many instances considered almost prohibitive, lack of anything like a normal foreign market, the present low value of farm products, stagnation in iron and steel, high costs of construction and general dullness of the retail trade stand out prominently as leading factors in the situation.

"Industry generally is optimistic and while the likelihood of a dull summer in most lines is fully recognized, the tendency is to count on improvement."

## Race Drivers Like Smaller Engines

### Speed Kings Believe 122 Inch Maximum Will Mean Industry Development

INDIANAPOLIS, July 11—Race drivers in Indianapolis are unanimously in favor of the new ruling of officials of the Indianapolis Motor Speedway to the effect that in 1923 cars entering for the 500 mile race will have to keep the piston displacement at 122 cubic inches as a maximum. The displacement in European cars would mean two litres. "Howdy" Wilcox stated to-day that it was his belief the action on the part of the Indianapolis race course officials would aid materially in developing the motor industry in this country. Louis Chevrolet, who designed two successive winners on the local course, also is in favor of the smaller displacement. Officials of the Duesenberg, while interested in the announcement, said that because they expected to retire from the racing game, they were not sufficiently interested to make any special experiments from a racing standpoint.

With the announcement of the reduction in displacement, Jean Chassagne, who was in the Ballot plant in France for some time and is said to be familiar with the creations contemplated and experiments tried, declares that before two years have passed the smaller engines will be making the speed the larger engines do. He said two two-litre cars now were being perfected in the Ballot and road trials prior to the Grand Prix in Le Mans showed them to make 95 miles. He believes that in another year the company will have perfected an engine that will compare in speed with those of larger displacements.

"Howdy" Wilcox is enthusiastic over the change. He said to-day that while the races might be uncertain the first year, yet some startling surprises would be recorded with the smaller engine. He like the others believed the second year would see the small engine on a par with the larger one. He is expecting a reduction of weights also. At the present time the minimum is about 1650 lbs. and he expects this to be reduced to about 1400 lbs. He says the small engine will produce as much speed eventually and the lighter car will enable the drivers to make some wonderful showings.

This is the fifth time that the Indianapolis track has reduced the engine sizes.

### START PROBE TO SOLVE THEFTS

NEW YORK, July 11.—District Attorney Lewis of Kings County will soon start investigating alleged collusion between owners of automobiles insured against theft and the thieves who steal them. The movement has been precipitated by the statement of an alleged thief who said he had taken the car in question under agreement with the owner so that he might collect insurance.

## Franklin Official Honored by Friends

**John Wilkinson, Inventor of Air-Cooled Motor, Has 20th Anniversary at Syracuse**

SYRACUSE, July 11—John Wilkinson, vice-president and consulting engineer of the H. H. Franklin Manufacturing Co., inventor of the first valve-in-head, four cylinder, air-cooled motor in America, the product of whose genius has developed into the world-known and esteemed Franklin automobile, made in the largest industry in the city, was guest last night at a reception to commemorate the twentieth anniversary of his start in the business and presented with a beautiful silver loving cup.

It was an intimate affair, this gathering at the showrooms of the E. W. Lawton sales agency, unusual in a city that is never slow to acknowledge and pay tribute to genius of her native or adopted sons, marked by expressions of regard and esteem of Franklin car owners and citizens of Syracuse generally. Among the crowd that heard sung the praises of the inventor and listened to him as with characteristic modesty he bestowed equal credit on the vision of H. H. Franklin and Alexander T. Brown, both of whom were present, were co-executives, salesmen, mechanics from the plant, leaders in the business and professional life of the city.

### Mayor Is a Speaker

Mayor Harry H. Farmer, William Allan Dyer, president of the Chamber of Commerce, and Frank H. Hiscock, chief judge of the Court of Appeals, were speakers introduced by S. Earle Ackerman, sales manager of the Franklin company, who paid tribute to the ingenuity of the inventor, his persistence in the face of obstacles, and praised him for the wonders he has wrought that have brought incalculable benefits to the city through creation of one of the great industries of the country.

Mayor Farmer represented the municipality officially. He referred to the wonderful advertising given Syracuse as the home of the Franklin car, greeted as a product of real merit in far off Japan, Alaska or the Antipodes and produced in a factory that has grown to be the largest of the many diversified industries here. He hoped Mr. Wilkinson would be spared in present vigor to participate in the celebration of the fiftieth anniversary which the mayor predicted as an even greater occasion than that of last night.

To Judge Hiscock was delegated the honor of speaking as the personal friend of Mr. Wilkinson, whom he has known since the flaxen-haired boyhood of the inventor to whom all paid tribute and has watched his career with a pride he made no effort to conceal in his remarks. John Wilkinson is one of those men who has been able to create something to

make life happier and more comfortable for his fellowmen, at least to have made a blade of grass grow where nothing had grown before, if he had not strictly complied with the scriptural recipe for blessedness by making two grow where one grew previously.

Two inventors whose names are inseparably linked with Syracuse it was his privilege to know quite intimately, Judge Hiscock said. First was the late John E. Sweet, who was so constituted he would rather put out a first class engine and sell it for what it cost him than to strive for the material returns alone, and the other was Mr. Wilkinson.

Sketching briefly the latter's career and paying tribute to his genius, industry and perseverance, Judge Hiscock wove into his informal remarks many little personal touches that revealed Mr. Wilkinson in a new light to some of those who do not know him so well, and also paid tribute to the confidence of Mr. Franklin and Mr. Brown in his invention, and the wise management that has built up the great industry making one of the best motor cars in the country.

## Reorganize Van Wheel; Make Extensive Plans

SYRACUSE, July 11.—The Van Wheel Corp. has been reorganized and is getting ready to go ahead in a much larger way. The new officers of the corporation consist of T. G. Meacham, president; J. W. Vanderveer, vice-president, and R. T. Wennstroom, treasurer and secretary. Meacham was formerly vice-president and general manager of the New Process Gear Corp. of Syracuse, now the New Process Gear Division of the Willys Corp. and is also president of the Meacham Gear Corp. Vanderveer is the inventor of the Van wheel and was also vice-president of the present company previous to the reorganization. Wennstroom was formerly comptroller of the H. H. Franklin Mfg. Co., and vice-president of the Walker Body Co. of Amesbury, Mass.

The corporation manufactures the "Van" hollow spoke cast metal wheel for both trucks and passenger cars. The truck wheel is of malleable iron, cast in four sections and electrically welded, which gives a true and concentric wheel.

### RUBBER FIRM FILES ANSWER

CLEVELAND, July 11.—The Columbia Tire & Rubber Co. of Mansfield has filed in the Federal Court here an answer to bankruptcy proceedings brought against it. All allegations are denied and a request is made for dismissal of the petition. The answer declares there is no merit to the claim of the Brighton Mills Co. for a large amount. Denial is made that the company is insolvent or that its funds were transferred to the Farmers Savings & Trust Co. It is asserted that only plant and equipment, not including quick assets amounting to nearly \$500,000, were transferred. The company asserts that after deducting all indebtedness the net assets amount to nearly \$1,000,000.

## Cameron Takes Over Sandusky Tractor

**Production of Engine Will Be Continued at Bridgeport Plant—Orders Are Steady**

NEW YORK, July 11—Cameron Motors Corp. has acquired the Dauch Mfg. Co., manufacturer of the Sandusky tractor at Sandusky, Ohio, and will continue the tractor business alone for the present, later adding production of the Cameron car. The plant containing 100,000 ft. of manufacturing space was said by President Cameron to be ample for the proposed needs of the company.

The tractor will be a light farm tractor similar to the one now turned out and the trade name Sandusky will be continued. The new product, however, will be equipped with a Cameron 4-cylinder air cooled engine and will sell at about \$425. These will be distributed through the dealer organization built up by the Dauch company, which numbers about 300 members.

Production of the Cameron engine will be continued at the Bridgeport plant of the Liberty Mfg. Co. under contract with the Cameron company. The rest of the tractor will be assembled at Sandusky. There will be no changes in the factory organization until complete plans are worked out covering production and sales.

Decision to manufacture the tractor only, for the present, was said by Cameron officials to be due to the unusual demand for this machine at this time. There are ample orders ahead and production will be speeded up to keep abreast of sales, but it is not expected to get into full production for at least a year.

## French Aviation Firms Are Now Consolidated

PARIS, June 25 (By Mail).—Three of the biggest French aviation companies: Astra, Nieuport and the Compagnie Generale Transaerienne have united their forces, with a capital of \$5,600,000, nominal exchange. The present offices and factory of the Nieuport company will constitute the headquarters of the new group, of which the general manager will be Marcel Thomas, at present with the Astra company, and chief engineer M. Delage, of the Nieuport company. The new group will be interested in both airplanes and airships, and has in hand an order for two hundred planes for the Japanese Government.

### PREST-O-LITE OFFICIAL DIES

INDIANAPOLIS, July 12—Announcement has been made of the death of Lewis N. Miller, 27 years old, assistant purchasing agent for the Prest-O-Lite Co., which occurred yesterday after an illness of several weeks. Mr. Miller served in the quartermaster corps of the United States Army.

# June Shipments Beat April or May

## Second Quarter 60% Same Period of 1920

### Report to N. A. C. C. Shows Surprising Production Record by Industry

NEW YORK, July 13—Shipments of automobiles for the month of June, as reported by the National Automobile Chamber of Commerce were 8 per cent larger than for May and virtually the same as in April. They reached 60 per cent of the mark set in June, 1920.

Carload shipments in June approximated 19,200, there were 18,000 driveaways and 3700 machines were shipped by boat.

Figuring boat shipments and driveaways in carload equivalents, shipments for the second quarter of this year nearly doubled the first quarter and were 61 per cent of the second quarter of 1920. Shipments for the second quarter of last year, excluding Ford, were 311,505. Shipments for the same period this year, therefore, were 190,018.

The figures since Jan. 1 by months compared with the same months of 1920 are:

	Carloads			Boats	
	1920	1921		1920	1921
January .....	25,057	6,485	Driveaways	1920	1921
February .....	25,505	9,986			
March .....	29,326	16,287			
April .....	17,147	20,187			
May .....	21,977	18,608			
June .....	22,516	19,200*			
1920	1921	1920	1921	1920	1921
29,283	3,185	....	93	....	93
43,719	7,507	....	99	....	99
57,273	9,939	....	75	....	75
64,634	14,197	....	1619	....	1619
74,286	15,193	....	2381	....	2381
60,746	18,000*	8350	3700*	....	....

\*Partly estimated.

These official figures demonstrate conclusively that the automotive industry is running on a better basis than almost any other in the field of manufactures. It proves also that the pessimism which prevails in many quarters is not well founded.

## Steel and Wage Cuts Bring Cheaper Cars

(Continued from page 87)

to-day. This means that the company has found a ready market for its products. George W. Bocker, president, says that June was an excellent month, with the factory running at capacity. He expects a satisfactory volume of business in the next six months. July has started off satisfactorily, with the factory operating at capacity.

Alexander Winton, whose keen intellect and executive capacity coupled with engineering skill, built up the Winton plant and established a reputation for the establishment, is devoting more time to production, with results that are satisfactory. Production in June was the greatest in any month of the year, and July promises to be about as good as June. The company plans to manufacture more cars in the next six months than it did in the first half of the year.

Jordan produced 30 cars a day in June and the schedule for the present month is about the same. M. S. Jordan, president, and Paul Zens, secretary of the company, left for Detroit Monday, July 11, for a conference with concerns from which they purchase parts and bodies. The reduction in the price of steel caused them to go to ascertain what benefits they may obtain from it.

At the Chandler and Peerless plants statements were made that factory operations were satisfactory, and business was good.

## Coast Sales Figures Prove Big Recovery

SAN FRANCISCO, July 12—The rapid recovery of the automotive industry on the Pacific Coast, and the steady return to normal were well illustrated at the end of June by figures issued by the State Motor Vehicle Department. These figures cover the entire State, but San Francisco dealers also declare that approximately the same proportion of increase holds good for Nevada and Arizona and for export trade as well, though not quite so strongly for sales in the states of Washington and Oregon.

The figures given out for the first four months of 1921, with comparisons for the same period of 1920, are as follows:

	1920	1921
Automobiles .....	421,982	540,339
Trucks .....	29,326	30,757
Trailers .....	1,699	2,456
Motorcycles .....	16,243	14,427

Conditions in the automotive industry in the East Bay section—Alameda, Oakland, Emeryville and Berkeley—are reported good by Manager Wert of the Oakland office of R. G. Dun & Co., in his summary for the closing week in June.

"Market conditions affecting retail sales of automobiles have fluctuated considerably in the past month. Some cars have had an unusual sale, while others have been slow. At present, sales are a little more active, due to recent price reductions. As a whole, conditions in the retail automobile field are quite satisfactory, and all the dealers seem to hold an optimistic air."

Some of the individual statements of sales and conditions, made in good faith by the dealers, show that Wert is too conservative.

## Cleveland Reaping Price Cut Harvests

### July Sales Get Start Well Ahead of Average of Several Years

CLEVELAND, July 11—Price reductions will make July this year a good month for the local retailer of automobiles, according to statements made by several dealers, who were visited at the close of the week July 9.

The first week of July started off with sales well ahead of the July average for several years. July long has been regarded as the first month of declining sales, but this year every dealer visited noted a stimulation of sales.

They accounted for this with the statement that price reductions are responsible. Many have been holding off buying new cars, waiting for price reductions. They have been encouraged to hold off by slight cuts here and there, but now that practically every car sold in Cleveland has been reduced in price and cuts have been very substantial, the buyer has become convinced that he will not profit by further delay. With the vacation days ahead and some of the best days for driving cars coming the car lover has come into the market with a rush.

"People are just beginning to realize that their dollar now will buy a hundred cents on the dollar of value in motor cars," said F. E. Stuyvesant, Hudson and Essex distributor. "This is true when judged by pre-war price standards."

The Barnes Motor Co., which has the Dodge agency, noticed no let-up in the demand for cars during the first week of July. The Chevrolet agency had a similar report to make with reference to the first week of July. New cars are moving easily, while used cars are harder to dispose of at this agency.

The Auburn agency will set a new record for July unless there is a complete upset in the outlook established by sales in the first week of the present month.

The Buick agency did as good business the first six days of this month as it did the first week of June. So did the Oakland, Overland, Willys-Knight, the Jordan, Peerless, Stearns, Templar and Franklin agencies.

## STOCKHOLDERS ORGANIZE

FORT WAYNE, IND., July 12—A. L. Jones, real estate dealer, has been named as president of the Revere Corp., a company organized among the stockholders of the Revere Motor Car Corp., of Logansport, for the purpose of purchasing the property of the defunct concern.

## South Africa Happy Over Sales Outlook

### Peace Treaty Progress Important Factor—Tractor Sales Promise New Records

JOHANNESBURG, SOUTH AFRICA, June 10 (By Mail)—The prospects for a good winter and the news that the matter of the Peace Treaty in Europe had become more settled has made country business very much brighter. Salesmen are all bringing in more optimistic reports, and better still, good sales records. The prospects for the second half of 1921 are very bright and distributors are looking forward to the gradual return to normal—normal in the sense that sales have been slack in the country districts. City conditions have not undergone much alteration and the steady demand remarked last month still continues.

Competitions and runs to stimulate interest in automobiles are being continually held in the different provinces and there is no doubt that they are having an effect. The reduction in the price of gasoline has been welcomed by dealers and the supply is now able to cope with the demand. The portion of South Africa that has felt the depression least is Rhodesia and conditions there have been fairly good. At present that country shows signs of being able to absorb large numbers of cars, and in proportion to the population is well supplied. As this territory is opened up the field for cars and trucks there will be very large.

#### Talk Better Roads

The automobile is becoming more recognized as the future means of transportation in this country and although prejudices against it are dying hard the internal combustion engine is gradually coming into prominence. The question of better roads—in consequence of more modern methods of transportation being adopted—is receiving the attention it deserves and the press has taken up a firm attitude on the point. In view of the estimates passed by the Provincial Council of the Transvaal cutting down expenditure on highways, the matter is being pressed more strongly and the general opinion is in favor of modern methods of road construction and maintenance.

The year 1921 is going to be the tractor year for this country and associations for the promotion of tractor sales have been formed in the large centers with results that are very gratifying. Trucks are being used for logging work in Natal and Cape Province over bad roads, and the results given are satisfactory. Figures showing the relative efficiency of ox traction as against the truck have been published in the daily press, and the mechanical vehicle scores heavily.

Great uneasiness is being felt by the motor trade in connection with taxation proposals. Up to the time of writing nothing definite has materialized.

## JULY SALES HEAVY IN WESTERN CITIES

NEW YORK, July 14—Dispatches received to-day by AUTOMOTIVE INDUSTRIES from correspondents in Salt Lake City, Des Moines, Denver and Dallas state without exception that automobile sales in the territories of which these cities are centers have shown an increase for the first two weeks of July over the corresponding period in June. The increase was particularly marked in the Des Moines territory.

### Normal July Business in New York District

NEW YORK, July 14.—Passenger car sales, which ran high throughout June in the Metropolitan territory, have dropped considerably during July up to date and the majority of dealers expect the falling off for the month to be more or less comparative with that which prevailed in normal years before the war.

Oldsmobile, Scripps-Booth and one or two other cars which had price reductions late in June after the novelty of most of the competing reductions had worn off sold better during the first two weeks in July than in previous months. However the normal run of cars, including the strongest sellers, have showed considerable dropping off in day by day sales.

The indications are that the July sales record will be considerably below June but nothing subnormal as July goes in New York city with a great many people in the automobile owning class out of town on vacations.

Notable sales records were made during June. Dodge sold at retail within the limits of New York city more than 400 passenger cars and 100 trucks. It is said that this has not been equalled except in cases where distributors included sales in outlying territories in their New York reports.

Nothing has developed to indicate that there will be any severe curtailment of buying during July and August. Dealers generally expect business to be slow but in this respect they will just be going back to normal conditions prevailing before the rush for cars in the past two years.

#### WINFIELD LAND PRICE LOW

PHILADELPHIA, July 13. — Judge Thompson in United States District Court here has set aside the sale of the Winfield Barnes Co. real estate holdings, consisting of a lot at Erie Avenue and Twentieth Street, 240x340 ft., and five buildings, which were bought at auction Monday by Morris & Kirby, attorneys for an unrevealed client, for \$73,500. The court ruled the sum to be inadequate. The sale at auction of personal property of the company including valuable machinery and equipment in 742 parcels to many purchasers was affirmed.

## Ohio Sales Improve as Car Prices Drop

### Buying Starts Anew in Columbus Territory—See Continued Good Business

COLUMBUS, July 12—There is quite a noticeable increase in sales with the passenger car dealers of Columbus and central Ohio since the price readjustments have taken place. Apparently the public was waiting for the reductions in price and with the announcements late in May and early in June, buying which had been held up for some time was started anew. As a result nearly all of the local agents and jobbers have been having a much better volume of business with prospects for the remainder of the summer extremely good.

It is the consensus that things will gradually improve in this section. The unemployment situation is not as bad as formerly and more of the factories are in operation. In some cases the output of manufacturing establishments has been increased and the financial as well as the business depression is being relieved to a certain degree.

The worst feature of the trade is the slowness still shown in the farming communities. Farmers are not having a good season as far as the wheat crop is concerned, which together with low prices is curtailing their purchasing power. This is shown in the less number of orders received for automobiles, principally passenger cars. The truck business in farming communities has suffered from the same cause.

Truck dealers are still having a slow business and little improvement is expected for the time being. Mercantile establishments are not disposed to increase their business equipment under existing conditions and consequently they are playing a waiting game as far as the purchase of trucks is concerned. Commission men and wholesale grocers are probably the best prospects at this time, and some trucks are being absorbed in those lines of industry. Haulage firms have sufficient equipment when the shrinkage in business is considered and they are not in the market to any extent. With the revival of business which is confidently expected in the fall a better demand for trucks is anticipated.

The repair business at the various shops and service stations in the Buckeye Capital is fairly good. Owners are coming in with their cars for minor repairs but generally they are postponing the general overhauling. Parts business is quite good, according to local agents.

#### CANADA SHOWS IMPROVEMENT

OTTAWA, ONT., July 11—During the fiscal year ending June 30, 1921, Canada exported vehicles, motor cars and parts to the value of \$2,591,995 to Australia, against \$2,119,955 for the previous 12 months.

## Verlinden Is Sued by General Motors

**Former Olds President Alleged  
to Have Loaned Self \$490,000  
Without Consent**

DETROIT, July 11—Suit was filed in Federal Court here to-day by the General Motors Corp. against Edward Verlinden, former president of the Olds Motor Works, to recover \$490,000 alleged to have been loaned to himself from Oldsmobile funds on deposit in Lansing, without the knowledge or consent of General Motors officials. Refusal of Verlinden to return the money upon demand of General Motors officials when the loan was discovered resulted in Verlinden's immediate dismissal, according to the petition filed in court.

The petition says Verlinden was employed as general manager of the Oldsmobile division under the usual written manager's contract providing for a salary plus a bonus on net earnings of the Olds division. The General Motors Corp. portion of the annual bonus was payable in stock of the parent corporation and held for a period of years in the custody of corporation in accordance with a written uniform plan. It is alleged Verlinden disputed deductions for depreciation in inventories and plants made by corporation accountants in order to reduce them to the market value, and also demanded, the petition says, that bonus shares of stock being held for him be delivered to him immediately although under corporation plan dividends during the period of retention of stock are paid to managers and employees whenever declared to other stockholders.

### Attorneys Issue Writs

Writs of garnishment against any and all funds to the credit of Verlinden in any Lansing bank were issued at the request of attorneys Stevenson, Carpenter and Butzel for General Motors. The suit resulted, it is alleged, from the action of Verlinden as assistant treasurer in countersigning a check on April 20. The check was drawn by Olds Motor Works division and payable to him against funds of the company in the City National Bank at Lansing for amount sued for. The check is said to have borne the notation "loan to Edward Verlinden." The petition recites denial of the plaintiff that it had knowledge of or authorized Verlinden to loan himself money for any such purpose or any other purpose.

### Counsel Justifies

#### Verlinden's Loan

DETROIT, July 11—The action of Edward Verlinden, former manager of the Olds Motor Works and vice-president of General Motors Corp., in drawing a check against the Olds account for \$490,000, is justified by E. C. Shields, attor-

ney for Verlinden, as accruing to Verlinden under the interpretation of his contract existing before the du Pont interests acquired control of General Motors.

In a statement covering the steps which led to the suit against Verlinden, in which the corporation asks restitution of the money, Shields declares there is a discrepancy of more than \$61,000,000 between the statement of 1920 earnings issued to stockholders, and the statement upon which President Pierre S. du Pont asked the Olds manager to adjust his contract bonus.

Owing to the unusual growth of the Olds division under Verlinden's management, the statement says, the manager was given a special contract under which he received a percentage of the earnings of the whole corporation. This contract was in force in 1918 and 1919 while W. C. Durant was General Motors head. During those years Verlinden's compensation under the contract was based upon net earnings without any special offsets, and he drew the amount from the Olds Motor Works account as he did in 1920.

### Profits Are Shown

At the end of 1920, however, the statement declares, President du Pont informed him that the profits of the corporation after deducting several charge-offs and write-downs, was \$32,000,000. At about the same time, the statement claims, the annual statement of the corporation for the year 1920 was issued showing net profits of \$93,150,308.

Part of a letter from President du Pont to Verlinden is quoted in the statement in which the executive says that, "it is possible that the profits of the several divisions of the corporation used as a basis for computing your compensation may appear out of line with the spirit of your compensation contract." Following receipt of this letter and several conferences in which he objected to the du Pont interpretation of his contract, Verlinden drew the adjustment check.

The statement says the manager immediately informed President du Pont of his check and advised him that he would pay the corporation as soon as the stock should be delivered to him. He contends that it was part of his contract that the stock of the General Motors Corp. that was held by the company in his name would be delivered to him whenever he or the company should sever connection with it. This stock, the statement asserts, has not been delivered to him.

Concluding, the statement says: "The whole controversy arose over special write-offs and write-downs which Mr. Verlinden claimed were not justified under the terms of his contract, and which Mr. du Pont persisted in making."

### OLD TIMERS GET NEW EMBLEMS

DETROIT, July 12.—Membership buttons in the Old Timers' Club are now being issued to accepted members by F. Ed. Spooner, secretary.

## Look Only for Minor Revisions of Taxes

**No Grounds for Assuming U. S.  
Treasurer Will Alter Original  
Recommendations**

WASHINGTON, July 12—It is believed that the Treasury's program for tax revision will contain only a few minor changes due to the movement of economic forces since Secretary of Treasury Mellon submitted his original recommendations to Congress last spring. There is no ground for assuming that the Treasury will recede from its previous declarations regarding the automobile industry. Just now the Advisory Board of the Treasury Department is comparing the fiscal needs of the Government with the estimated yield from the proposed tariff schedule and proposed tax rates.

The House Committee on Ways and Means will undertake the study of tax revision about August 1, when it is expected that the tariff bill will be sent to the Senate. The Senate Finance Committee conducted hearings on the internal revenue legislation for several weeks last spring under an arrangement with the House Committee on Ways and Means, in order to expedite the passage of the revenue law. Because of this action, the Senate Committee will be in a position to dispose of the House tax bill without long hearings and the whole measure should be enacted before September 15, provided the Congress quits bickering over various items.

While the Treasury has made no public announcement of its plan, it is known that Secretary Mellon is dependent upon the advice of Professor P. S. Adams, Chairman of the Tax Advisory Board of the Treasury. Prof. Adams is known to favor the replacement of the excess-profits tax by a tax on the undistributed profits of corporations; the repeal of existing sales or consumption taxes on fountain drinks, "luxuries" and medicinal articles, and the introduction or increase of a few miscellaneous taxes, chiefly on articles of widespread but not absolutely essential consumption, selected largely on ground of administrative convenience.

## Ford Cuts Inventory \$33,000,000 in Year

BOSTON, July 11—The Ford Motor Co., Inc., under the laws of Delaware, has filed with the Commission of Corporations of Massachusetts the following statement, dated April 30, 1921:

	1921	1920
Real estate.....	\$71,329,719	\$85,649,727
Machinery .....	46,459,046	41,661,137
Merchandise .....	63,848,157	96,859,012
Cash & acct. receiv...	86,995,166	62,499,027
Securities .....	10,361,963	18,921,608
Accounts payable.....	44,993,755	15,958,116
Notes payable.....	3,892,386	35,112,974
Surplus .....	182,877,686	165,679,132

## White Celebrates 20th Anniversary

### Branch Managers Dine Brothers and Recall Early Days of Industry

CLEVELAND, July 11—Windsor T. White, chairman of the executive board, and Walter C. White, president of the White Co., were given a dinner to-night by the branch managers met in annual conference and to celebrate the twentieth anniversary of the White brothers in the manufacture of motor vehicles. All of the branch managers of the United States and Canada together with a few invited guests were present.

During the dinner J. S. Hathaway, manager of the Boston branch, and who in years of service is the dean of the branch managers, having been connected with the sale of White vehicles since the company started, presented the brothers, on behalf of the branch managers, with a miniature of the first White steam Stanhope built 20 years ago. It is a complete miniature made one-fifth size, and having every detail worked out with the exception of the internals of the power system. Fred S. Bonton of Cleveland, who purchased the first steam car built by the Whites on April 27, 1901, was among the guests and told of early experiences.

#### Colonel Clifton Speaks

Col. Charles Clifton, president of the National Automobile Chamber of Commerce and whose connection with the Pierce-Arrow Co. dates back 20 years, told of his close friendship with Windsor T. White from the days of the now famous New York-Pittsburgh Mud-lark Tour in the fall of 1903. Colonel Clifton was the only representative of the manufacturing industry present.

George Urquhart, manager of the White San Francisco branch, who presided as toastmaster, in introducing Hathaway suggested some early reminiscences which resulted in an intimate sidelight on business ethics as expressed by Windsor White to Hathaway 20 years ago. He emphasized as a cardinal principle, "We can stand for an honest failure but cannot stand for a dishonest success."

Windsor White in his family talk to the group added interest by drawing attention to two old employees whose years of service date to the early days of the late Thomas White, organizer of the White Sewing Machine Co. One of these employees has been in the White service for 43 years, and the other for 40 years. They have already served under three generations of the Whites. Length of service does not all go to the employees, as the average years of association of the branch managers present with the company was 12 out of a possible 20 years of representation.

Roland H. White, president of the Cleveland Tractor Co., and the third of the brothers, who withdrew from the

White company at its reorganization and started tractor development, was one of the guests. David Beecroft, president of the Society of Automotive Engineers, and directing editor of the Class Journal Co., spoke on some future aspects of the industry.

### Jacoby Named Head of Mitchell Motors

NEW YORK, July 13—William L. Jacoby, an efficiency engineer and industrial expert for A. G. Becker & Co. for the past ten years, has been elected president of the Mitchell Motors Co., Inc., Racine, Wis. He succeeds D. C. Durland who has returned to the General Electric Co. with headquarters in Chicago. Durland remains a director of the Mitchell company.

Mitchell Motors is controlled by Becker & Co. and Ladenberg, Thalman & Co., of this city. Jacoby was placed in charge of the company's affairs because of his ability as an industrial executive. He has directed in the past many of the industrial enterprises in which Becker & Co. have acquired an interest. His home is in Chicago.

The retirement of Durland is understood to have been voluntary and the position he has taken with the General Electric is considerably more important than the one he relinquished.

The Racine company is coming back rapidly and its sales for June were the heaviest for any month in nearly two years. Sales for the first ten days of July went ahead of the June record for that period. The outlook for the company is decidedly encouraging. Its inventory has been reduced to normal proportions and material reductions have been made in its obligations.

#### DISBROW NOW A MANUFACTURER

CHICAGO, July 13—Louis Disbrow, racing veteran, has entered the field of spark plug manufacture. He is vice-president and engineer of the Victory Co., of Milwaukee, making a plug in standard sizes and with metric extensions, and will make his headquarters at 2118 Michigan Avenue, this city, where sales headquarters will be maintained. He is also representing the Dow Chemical Co.'s line of pistons and hose clamps.

#### WHOLESALE GAS PRICES DROP

NEW YORK, July 12—Wholesale prices on gasoline have now decreased about 28 per cent since Jan. 1, the price in 30 principal cities averaging to-day 21.1 cents a gallon. The lowest quotation is 15 cents a gallon at Kansas City, Mo., and the highest 26 cents at Seattle. Prices have declined only 2 cents a gallon in California and Washington since Jan. 1.

The New York wholesale price to-day is 24 cents, a drop of 7 cents since Jan. 1. In San Francisco the price is 25 cents, a 2 cent drop. Chicago is selling at 18 cents, New Orleans at 19.5, a 9 cent drop in each case.

## Creditors Favorable to Denby Bond Issue

### Certain More Than 75 Per Cent Will Agree to Plan for Work- ing Capital

DETROIT, July 13—Creditors of the Denby Motor Truck Co. at a meeting yesterday showed an inclination to join whole-heartedly in the plan of the creditors' committee to issue bonds and first preferred stock in settlement of claims and for raising the necessary capital.

Twenty-five per cent of the merchandise creditors signed up at the meeting and those not present are sending in signed agreements by mail assuring favorable action by 75 per cent, according to members of the committee, which permits the plan to become operative.

The plan of the committee is to issue 100,000 class A first mortgage bonds to be used in the discretion of the directors for imperative current needs as working capital; 200,000 class B first mortgage bonds to be prorated among creditors, which is equal to about 25 per cent of the total indebtedness, and first preferred stock in an amount sufficient to cover the remainder of all claims, this stock to have priority over all existing stock, both preferred and common. The present preferred stock, of which there is \$228,100 outstanding, would become second preferred. There also is outstanding \$474,930 common.

Seventy per cent of the present stockholders have deposited the holdings with the Security Trust Company to be voted favorably on the committee plan which will become operative automatically when 75 per cent of the stockholders' and creditors' claims have agreed.

### Durant Men in New York Will Discuss Policies

NEW YORK, July 11—Chiefs of the various divisions of Durant Motors are here this week for conferences with Durant on questions of general policy. Among those in New York for the meeting are T. W. Warner, Edward Verlinden, who will have charge of the main Durant plant at Lansing, and D. A. Burke, who developed the Sheridan.

Rapid progress is being made in building up a dealer organization, particularly in the East, where the work is under the direction of M. D. Leahey. Dealer relations are being established in the central territory by Verlinden and on the West coast by E. M. Steves, general sales manager for Durant Motors of California.

#### JENKINS SUCCEEDS HAMPTON

NEW YORK, July 13—Uncertainty concerning the successor to E. H. Hampton as manager of the assembly plant of the Ford Motor Co. at Buenos Aires, Argentina, is cleared up by an announcement of the company that H. S. Jenkins is in charge of the Argentina branch.

## NEW CAR PRICES

## APPERSON REDUCES CARS

KOKOMO, IND., July 12—Reductions ranging from \$250 to \$750 have been made, by the Apperson Bros. Automobile Co. on open cars in both its Standard and Anniversary models. The Standard 4-passenger is cut from \$3,500 to \$3,000, and the 7-passenger from \$3,500 to \$3,250. The Anniversary 4-passenger is reduced from \$4,250 to \$3,500, and the 7-passenger from \$4,250 to \$3,750.

## ELCAR PRICES COME DOWN

ELKHART, IND., July 11—Elkhart Carriage & Motor Car Co. has reduced prices on all models of Elcar in announcing its 1922 line. In the open cars the De Luxe models are reduced from \$1,700 to \$1,595, the Standard models are priced at \$1,385, and the lighter models are reduced from \$1,300 to \$1,195. In the enclosed cars the 3-passenger coupé is reduced from \$2,500 to \$2,395 and the sedan from \$2,600 to \$2,495.

## ALL HOLMES MODELS CUT

CANTON, OHIO, July 11.—Holmes Motor Car Co. has reduced prices on all models \$400. The four and seven-passenger models are reduced from \$3350 to \$2950, the coupe from \$4250 to \$3850, and the sedan from \$4550 to \$4150.

## KLINE CUTS OPEN CARS

RICHMOND, IND., July 11—Prices on Kline open models have been reduced \$200 by the Kline Kar Corp., the new prices on the roadster and touring models being \$2,090. The enclosed car prices are continued as formerly.

## HAWKEYE TRUCKS REDUCED

SIOUX CITY, IOWA, July 11.—Prices on Hawkeye trucks have been reduced from \$265 to \$645. The 1½ ton is cut from \$2365 to \$1850, the 2-ton, \$2915 to \$2650, and 3½-ton, \$4345 to \$3700. Under the new management plans as inaugurated two months ago, the company reports a gradual increase in business.

## CUT PRICES ON KLAXON HORNS

NEWARK, N. J., July 11.—Prices on Klaxon horns have been reduced on all models, the price change ranging from 75 cents to \$3. In the future push buttons and wires will be furnished only with the Klaxon 20. With models 6, 6-Deck, 6-MC and 5 this equipment will cost 75 cents list, and with models 12 L and 12 S, will cost \$1 list.

## PORTAGE FILES ACCOUNTS

AKRON, OHIO, July 11.—Schedules in bankruptcy showing liabilities of \$5,438,993 and assets of \$5,074,337 have been filed in the United States district court at Cleveland by the Portage Rubber Co. of Akron, the papers being signed by M. S. Long, president. The company was thrown into the hands of receivers May

31, George D. Bates and John W. Maguire being named receivers. Maguire is vice-president and general manager of the company.

Notes and bills amounting to \$3,444,320 constitute the largest items in the liabilities listed. Unsecured claims totaling \$1,743,353 are also listed. Among the company's assets are listed real estate at \$660,994, stock in trade \$834,384, and machinery and tools \$1,889,880.

Leland Denies Lincoln  
Refinancing Reports

DETROIT, July 11—W. C. Leland, president of the Lincoln Motor Co., made the following statement to-day in reference to persistent reports of a reorganization and refinancing of the company:

"Our factory was closed last week for inventory and reopened this morning as it was announced it would do when we shut down. There is absolutely no truth in reports of any reorganization of this company or any change whatever in management. Any report that there is a big refinancing plan under negotiation also is absolutely false."

Sixty per cent of the normal force will be at work, he said, and about seventeen cars will be built daily.

## HARVESTER TRACTORS DOWN

CHICAGO, July 12—International Harvester Co. to-day reduced prices on three of its tractor models. Titan 10-20 is cut from \$1,000 to \$900, International 8-16 \$1,000 to \$900, and International 15-30 from \$1,950 to \$1,750. Each of these models is equipped with friction clutch pulley and angle lugs. The new prices are effective at once. In the case of the International models the price is the lowest ever quoted. With the equipment now included on the Titan the price too is lower than ever before. In announcing the new prices the company declares that all war time advances are wiped out and the products placed at a more favorable price than ever before.

## DUESENBERG ELECTS OFFICERS

INDIANAPOLIS, July 13—Reorganization of the Duesenberg Automobile & Motor Co., Inc., has been completed by the election of the following officers: President, B. A. Worthington; vice-president and general manager, L. M. Rankin; secretary and treasurer, F. A. Reilly; chief engineer, F. S. Duesenberg; assistant chief engineer, A. S. Duesenberg; assistant engineer, E. J. Porter; sales manager, Harry W. Anderson; purchasing agent, George H. Beilstein.

## CORBITT TRUCK REDUCED

HENDERSON, N. C., July 11—Corbitt Motor Truck Co. has reduced prices on all models from \$200 to \$500. Reductions on the 1-ton are from \$2,400 to \$2,200, the 1½-ton, \$2,800 to \$2,600; the 2-ton, \$3,500 to \$3,150; the 2½-ton, \$3,650 to \$3,300; 3½-ton, \$4,500 to \$4,100, and 5-ton, \$5,500 to \$5,000.

## METAL MARKETS

MATURE reflection of the situation brought about in the steel market as the result of the downward revision in "official" prices can not help but convince the automotive purchasing agent that henceforth steel values will sail a more even course. It was only natural that announcement of the price changes should be followed by the question when the next cut in prices will eventuate, this on the ground that steel price levels are still 50 per cent higher than they were before the war. Leaders in the steel industry took particular pains to anticipate this question by accompanying announcement of the price changes with a showing that, eliminating the compulsory increment of prices as the result of the advance in freight rates and wage scales over those of 1913, steel prices now rule lower than they did before the war. This is only another way of saying that further reduction in prices must wait upon a lowering of freight costs and wage scales.

At the present there is no representative demand for steel. Hand-to-mouth buying is looked for to continue for some time, except perhaps by the railroads which are now expected to lead the way in committing themselves as buyers by contracts, once the financial arrangements with the Treasury, now under way, are completed. When, however, a sufficiently large demand develops from sources other than the railroads to warrant the placing of contracts for deferred deliveries, buyers will naturally bethink themselves of contracts that will protect them in the event that reductions in freight rates and wage scales will make further shading of prices possible. Good, although perhaps slow progress is being made in the matter of deflating wage scales. Of special interest to the automotive industry in this connection is the 10 per cent cut in wage scales assented to by the Amalgamated Association of Iron, Sheet and Tin Workers at its conference with the Western Sheet and Tin Manufacturers' Association in Columbus. For the time being the smaller interests among the "independents" will endeavor to secure what business offers at the "stabilized" prices announced by the larger interests. It is not likely that this program will be altered, unless the slight quota of orders which the small mills have at this time should be still further curtailed. All in all, the outlook for the entire steel industry is growing brighter and slow gains in orders are looked for by even the most confirmed pessimists of a few weeks ago.

Pig Iron.—With sales of retail proportions, values continue plastic. Malleable has been sold at \$21.50, Buffalo, furnace.

Steel.—The full-finished sheet price, in keeping with the general reductions on sheets, is now at 4.70c. for 22-gauge auto-body stock. Full-finished sheet makers in the Youngstown district have a fair amount of orders on hand. Some inquiries for strip steel have been put out by Detroit passenger car builders. Prices for hot-rolled and cold-rolled strip steel appear to be still in the making. Inquiries for bolts and nuts are more numerous in spite of the fact that most of the passenger car builders are reported to have large stocks on hand.

Aluminum.—So far market quotations have not been assisted in the least by the possibility of the tariff on aluminum being adopted as recommended by the Ways and Means Committee. Consumers appear to incline to the view that the aluminum schedule will come in for so much criticism in the House that it will be altered.

## FINANCIAL NOTES

**Timken-Detroit Axle Co.**, in a comparative balance sheet as of Dec. 31, shows assets for 1920 as \$21,494,863, as compared with \$22,697,214 for 1919. Cash on hand Dec. 31 is shown as \$671,151 and inventories total \$10,932,521. The cash position represents a reduction of about \$800,000 from the year previous and the inventories are about \$700,000 more. The company's surplus is \$9,866,662, as compared with \$10,175,580 in 1919. A \$100,000 reserve for contingencies is set forth.

**Firestone Tire & Rubber Co.**, in a comparative balance sheet as of Oct. 31, shows total assets of \$107,404,200, as compared with \$73,753,598 in 1919. In the 1920 balance inventories are set out as \$45,163,710, an increase of \$21,000,000 over 1919. Cash and government securities total \$5,198,060, approximately the same total as the year before. A surplus of \$33,880,757, depreciation reserve of \$8,098,495 and \$3,151,750 reserve for inventory loss are set forth.

**Herschell-Spillman Motor Co.**, in a comparative balance sheet as of Dec. 31, reports assets of \$3,857,452 as compared with \$2,409,297 for the year previous. Cash is set forth as \$120,337, and inventories \$1,402,318. The inventory total for the year before was \$553,003, and the cash \$586,798. The surplus for 1920 was \$35,527 as compared with \$71,610 for the year before. Reserves are carried totaling \$122,819.

**Lee Rubber & Tire Corp.** reports current earnings running well ahead of dividend requirements. Decreased production records for the first quarter of the year have been followed by record production in the second quarter, which is continuing. Total bank debt is declared to be \$500,000 and cash on hand is said to exceed that amount. Inventories are declared to be normal.

**Buda Co.**, in a comparative income account dated Dec. 31, shows gross sales of \$8,721,884 for 1920, as compared with \$7,432,287 in 1919. Net income for 1920 was \$329,261, as compared with \$405,789 in 1919. The balance sheet dated Dec. 31 shows total assets of \$5,826,617, in which inventories total \$2,413,840 and cash \$309,778. Surplus and undivided profits total \$1,834,905.

**Falls Motor Corp.**, in a balance sheet as of Sept. 30, 1920, shows total assets of \$3,461,256, in which is included cash of \$161,303 and an inventory of approximately \$800,000. The surplus of the company is \$35,933. Accrued dividends total \$98,210, accrued wages \$15,796 and accrued taxes \$41,544.

**Kelsey Wheel Co.** reports business at a rate which indicates earnings on a par with the \$1,916,000 net profits of 1920. The balance sheet as of Dec. 31 showed total assets of \$22,680,911. The company is supplying the Ford Motor Co. with a large part of its wheel requirements.

**Mitchell Motors Co.**, in a comparative balance sheet as of Dec. 31, shows assets of \$8,846,208, as compared with \$8,667,794 for 1919. Cash is shown as \$82,339 and inventories as \$5,188,761. The company's surplus is \$3,952,129 and reserve for contingencies \$142,750.

**H. H. Franklin Mfg. Co.** paid a dividend of 50 cents a share on common stock on July 11. Forty per cent of employees are now stockholders. Profits for the first five months of 1921 are estimated to be in excess of \$775,000 after taxes.

**Wright Aeronautical Co.** reports orders ahead, which indicate a gross business for the year in excess of \$2,500,000, and declare

earnings will approximate \$1.38 a share, as in 1920, after charges and allowances for development expenses.

**International Harvester Co.**, through Vice President Legge and Treasurer Ranney, declare the company is not contemplating any new financing. Not much change in the affairs of the company in a monetary sense is expected this year.

**Flak Rubber Co.** directors have deferred action on dividends on both first and second preferred stock. The last disbursement on the second preferred stock was 1½ per cent on June 15, and on first preferred 1½ per cent on May 1.

**Ajax Rubber Co., Inc.**, through its board of directors, has declared that no new financing is contemplated and that the company was in no need of additional funds. The business outlook is reported better than for months.

**Republic Motor Truck Co., Inc.**, in an income account for the March quarter, shows net sales as \$797,163, profit after sales costs of \$143,778, gross income of \$174,163, and a deficit after expenses, charges, etc., of \$367,808.

**Fisher Body Corp.** has declared a dividend of 1½ per cent on its preferred stock, to be paid Aug. 1. A dividend of \$2.50 a share will be paid at the same time on the no par common stock of the company.

**United States Rubber Co.** has passed payment of the quarterly dividend of common stock due at this time. The regular quarterly dividend on the first preferred will be paid July 30.

**Wright-Fisher Bushing Corp.** has gone into receivership, the Security Trust Co. of Detroit being appointed to take over the affairs of the company.

**Hale & Kilburn Corp.** report American Body Corp. sales from Aug. 11, 1920, to Dec. 31, 1920, as \$8,523,875. Net income after all expenses was \$269,457.

**Hupp Motor Car Co.** declared the regular quarterly dividend of 2½ per cent on the common stock, payable August 1 to stock of record July 15.

**Electric Storage Battery Co.** has declared regular quarterly dividends of \$3 on both the common and preferred stocks, payable Oct. 1.

**Federal Rubber Co.** has omitted the quarterly dividend of 1½ per cent on first preferred stock due at this time.

## Toledo Plants Re-employ 8288 Men During June

**TOLEDO, July 15.**—The employment situation in Toledo has been greatly relieved in the last month mainly by the awakened activity at the plants here which are associated with the automotive industries. Out of 26 cities of the country showing a gain, Toledo was third, with 15.6 per cent betterment in June.

The report of the Merchants' and Manufacturers' Association here shows that during the month Toledo plants requisitioned 13,738 men, of whom 8288 were vehicle workers, and most of them taken back to work by the Willys-Overland Co.

In addition to this number of automobile men there were put to work 485 textile workers, 1533 iron and steel workers, 1987 clay, glass and stone workers and 1408 miscellaneous employees.

## BANK CREDITS

*Written exclusively for AUTOMOTIVE INDUSTRIES by the Guaranty Trust Co., second largest bank in America.*

**NEW YORK, July 12.**—The reserve ratio on the Federal Reserve System declined slightly from 60.8 per cent to 60 per cent. This was largely a result of the \$37,441,000 increase in Federal Reserve notes in circulation, as well as the \$27,364,000 increase in deposits. Gold reserves increased \$15,875,000 and total discounts \$29,801,000.

Money was in somewhat larger supply on the local money market last week following the mid-year disbursements. Call money had a slightly narrower range at 5½ per cent to 6 per cent, as compared with 5 per cent to 6 per cent the previous week. The ruling rate was 5½ per cent although on the "outside" market some trades were made at lower rates. The larger supply of funds also had an effect on the quoted rates in the time money market. Six per cent was quoted for all periods from 60 days' to 6 months' as against 6½ per cent for 60 days' and 4 months' paper and 6 per cent to 6½ per cent for 5 and 6 months' paper a week ago. The market, however, was quiet and transactions were not made on a large scale. In the commercial money market 6½ per cent to 6½ per cent was quoted for 60 and 90 days' indorsed bills receivable and 6 months' prime bills as against previous rates of 6½ per cent to 6½ per cent.

The significant feature of the industrial world last week was the action of the United States Steel Corporation in reducing prices, following the lead of the Bethlehem Steel Corporation. The two price reductions now made since April by the Steel Corporation from the price maintained from March 21, 1919, to April 12, 1921, the level established by the Industrial Board, range from \$8 to \$25 per ton for steel products. The present prices are now about 29 per cent below the "Government prices" during the war, and 17 per cent below Secretary Redfield's Industrial Board prices. In addition, the Steel Corporation also abolished the time-and-one-half wage scale for overtime work. These two decisions should have a beneficial effect toward putting the steel industry on a readjusted basis. The industry is now working much below normal as compared with the general level of activity in the industrial field throughout the country. The present rate of operation was estimated to be about 20 per cent of capacity.

## SPEED REFINANCING PLANS

**NEW YORK, July 12.**—Marked progress in the plans for refinancing the Willys-Overland Co. were made at a meeting of the bankers' committee today. It is expected that details of the plan will be announced in the near future. The basis of the refinancing plan will be the issuance of first mortgage bonds, the proceeds of which will be used to take up the floating debt.

## MEN OF THE INDUSTRY

Charles Hendy, Jr., identified for the past fourteen years with the Ford Motor Co., has announced his connection with Simplex Corporation of Chicago, manufacturers of Theftproof Auto Locks. Mr. Hendy was for many years in charge of the Denver plant of Ford Motor Co., and for the past two years has been manager of the Chicago plant. He acquires a stock interest in Simplex Corporation and becomes vice president and general manager. To date, Simplex Corporation has devoted its output to extra locks, but under Mr. Hendy's management will actively push its factory type lock for standard equipment.

A. G. Selberling of the Haynes Automobile Co. at Kokomo, Ind., has been named chairman of the special committee of the Kokomo Chamber of Commerce to co-operate with the board of directors of the Howard County Automotive Trade Association in putting on an automobile show and industrial exposition next September. At a meeting of the Automotive Trade Association results of the co-operative used car market, which was held recently, were discussed. So successful was the market that it has been decided to hold another some time the latter part of July or the first of August.

Albert R. Erskine of South Bend, the managing head of the Studebaker corporation, has been named as one of the members of the interstate harbor commission of Indiana and Illinois, created by an act of the last session of the General Assembly. The commission is to investigate the feasibility of the construction of a proposed interstate harbor in Lake Michigan in the Calumet district of Indiana and the Chicago district of Illinois. Two members are to be appointed by the Governor of Indiana, two by the Governor of Illinois and one by the Secretary of War.

C. P. Raney, who has been assistant manager of the Miller Tire Repair School since June, 1919, has accepted a position as Akron branch manager for the Western Rubber Mold Company. Mr. Raney has had nine years' experience in the rubber industry. In 1913 he was tube inspector of one of the Akron companies. This work was followed by a position as department foreman. He later became an industrial engineer for another of the large tire companies.

Frederick C. Horner, formerly transportation engineer of the Packard Motor Car Co. of New York, has sailed for England, where he will spend a year studying various transportation matters. He will make London his headquarters during his work abroad, and plans to spend some time in Scotland and on the Continent. He intends particularly to study carefully the operating program of the London General Omnibus Co.

Mr. Robert D. Black, who was formerly assistant sales manager of The Black & Decker Mfg. Co., of Towson Heights, Baltimore, Md., has been appointed manager of the company's Philadelphia branch office. Mr. Black succeeds Mr. W. C. Allen, who has been made a special factory representative, with headquarters at the Company's Cleveland Branch Office.

Herschel C. Smith, formerly deputy state highway engineer of Oklahoma, has been appointed assistant professor of highway engineering and highway transport at the University of Michigan, from which institution he graduated in 1913. Last June he

received the degree of Master of Science in Highway Engineering and Highway Transport.

F. W. Fenn, secretary of the motor truck committee of the National Automobile Chamber of Commerce, has gone to Canada for a three-weeks' vacation, after a month's trip through the Middle West, in which he visited many truck plants which are non-members of the chamber.

H. L. Dunn, purchasing agent for the Handley-Knight Co., has tendered his resignation, to take effect Aug. 1. He has not announced his plans for the future.

Charles L. Derrickson, of the McQuay-Norris Mfg. Co., St. Louis, has been discharged from the hospital after a serious illness of four months.

## INDUSTRIAL NOTES

Franklin Automobile Co. announces that from January 1 to June 30 it produced and sold to dealers 5382 cars having a retail value of \$17,784,000. This represents 82 per cent of the number turned out and sold during the corresponding period last year. In June 1938 cars were shipped. On June 24 the production schedule was increased from forty cars daily to forty-three.

Lincoln Motor Co., starting with fifteen distributors in November, 1920, has increased the number of distributors and dealers to 138. Sales reflect the contracts. Each month of the second quarter has bettered the entire first quarter's business.

Rhode Island Machine & Tool Co. of Woonsocket has been licensed to manufacture high pressure greasing devices under the Bassick patents, and patent litigation between the two companies has been withdrawn.

Samson Tire & Rubber Corp., Los Angeles, is operating on a 24-hour daily schedule to meet heavy sales demand for its product.

Root and Van Dervoort Corp. produced 450 cars in the first half of the year, as compared with 767 in all for 1920.

## N.A.C.C. Directors Get Reports on Activities

BUFFALO, July 13—Several subjects of interest to the industry were discussed by directors of the National Automobile Chamber of Commerce at a meeting here to-day at the Hotel Lafayette. One of them was a greater degree of co-operation with automobile dealers throughout the country. In this connection a report was made on the conference held here yesterday between committees representing the N. A. C. C. and the National Automobile Dealers' Association. Directors were asked to adopt a definite plan for co-operation with Secretary of Commerce Hoover in assembling industrial statistics and promoting foreign trade.

The directors also took up the program for promoting "safety first" plans on a national scale including the use of a \$5,000 fund to be given in prizes to school children for essays.

Alfred Reeves, general manager, stated that reports submitted at the meeting showed that the automobile business is 10 per cent better off than any other industry.

Directors who attended the meeting were R. E. Olds, Charles D. Hastings, Alvin Macauley, A. J. Brosseau, John N. Willys, H. H. Rice, H. M. Jewett, W. L. Pulcher, Thomas Henderson, J. Walter Drake, W. E. Metzger, Roy D. Chapin and C. C. Hanch.

## Detroit to Have Annual Convention of M.A.M.A.

NEW YORK, July 12—This year's credit convention of the Motor and Accessory Manufacturers' Association will be held at the Hotel Statler, Detroit, Wednesday, Thursday and Friday, Sept. 14, 15 and 16. Tentative plans call for a comprehensive and vital program of papers and discussions, built around the central theme: "Bringing the Automotive Industry Back to Normal."

Detroit was selected this year because of its convenience to the great majority of the 400 companies affiliated with the association. Speakers of national importance from the automotive industry and from industrial, banking and governmental circles will be scheduled for the program. The annual credit convention of the M.A.M.A. is usually regarded as one of the industry's most significant gatherings, for there the credit managers, financial directors and general executives of the unit and equipment manufacturers exchange comments and experiences on current conditions and future prospects for the automotive field.

## Rubber Association Men Study Proposed Tariff

NEW YORK, July 12—General Manager A. L. Viles of the Rubber Association of America will take up immediately with President Harry T. Dunn and directors of the association, a study of the 10 to 35 per cent duty on tires proposed in the permanent tariff measure now before Congress.

Probable effect of the proposed increase of 25 per cent in the duty on foreign made tires will be discussed and a policy determined upon. Though it is recognized that no high tariff protection is needed now, Viles said there were some tire makers who thought competition would develop as production methods improved abroad.

Probability of retaliatory action by importing countries will be considered as having an important bearing on the future of the tire industry in this country, Viles said.

## AUTOMOTIVE CORPORATION SUED

TOLEDO, July 15—Ten residents of Cleveland filed suit in Common Pleas Court here this week to recover money paid to the Automotive Corporation for stock. They claim that false representations were made by agents of the company.

# Calendar

## SHOWS

Sept. 5-10—Indianapolis, Automobile and Accessory Show in conjunction with Indiana State Fair, conducted by Indianapolis Automobile Trade Association, John B. Orman, Mgr.

Sept. 28-Oct. 8—New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January—Chicago, Automobile Salon, Hotel Drake.

Jan. 7-13—New York, National Automobile Show, Madison Square Garden, Auspices of N.A.C.C.

Jan. 28-Feb. 2—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.

## FOREIGN SHOWS

September—Buenos Aires, Argentina, Passenger Cars and Equipment, La Pabellon de las Rosas, Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery, Palermo Park, Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Sept. 23-Oct. 2—Berlin, German National Automobile Show, Auspices of German Automobile Mfg. Ass'n and German Automobile Club.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

## CONVENTIONS

Sept. 14-15-16—Portland, Ore., Credit Convention Motor

and Accessory Manufacturers Association.

Oct. 12-14—Chicago, Twenty-eighth Annual Convention National Implement & Vehicle Ass'n.

Nov. 22—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

## RACES

July 25—Grand Prix, Le Mans.  
Labor Day—Uniontown, Pa., Autumn Classic.

## Bosch Magneto Adds Battery Ignition System

BRIDGEPORT, CONN., July 12—The American Bosch Magneto Corp. has announced the addition to its line of electrical equipment of a battery ignition system. This system is not intended to displace the magneto ignition system, which will be continued, but to supplement and complete a line which, according to the announcement, is intended to satisfy every electro-mechanical need of the automotive industry.

The battery ignition system comprises a timer-distributor and a coil. The distributor is made in two types, the so-called "compensating" or automatic advance type, and a type suited for manual control. Both systems are provided for 4, 6 and 8 cylinder engines. The coil, arranged for mounting on the engine side of the dash or on the engine, as desired, is inclosed in a tubular case with molded ends, and is assembled with a single through bolt in the axis of the coil. The coil is said to be dust- and waterproof. A ballast coil is provided to adapt the system for operation on either 6 or 12 volts.

## Fort Wayne Druggist Buys Rubber Company

FORT WAYNE, Ind., July 12.—David S. Vesey, trustee in bankruptcy, has accepted the bid of \$90,000 cash made by Henry J. Bowerfind, president of the Fort Wayne Drug Co., for the property and equipment of the bankrupt Fort Wayne Tire & Rubber Mfg. Co. The bid will now have to be accepted by the referee in bankruptcy.

Several other bids were made for the property at the trustee's sale. Among these was a bid of \$90,000 by the stockholders of the concern, but as this bid was for part down and the rest on time payments the bid was not accepted. A Chicago concern bid \$95,000 on time for the plant and a Cleveland company \$110,000 on time, but these bids were also turned down because of the time element in the payments.

The total indebtedness of the local concern is about \$200,000, outside of the

amount put in by the stockholders, of course. The total appraisement of the property, including claims, was \$263,000. The plant owns two and a half acres of ground and a three-story, 100 by 150 ft. building. The building and land were appraised at \$160,000 and the equipment at \$100,000.

The appraisement is considered quite high on the basis of present costs. The machinery and stock were purchased at a time when prices were highest and the building was erected during the era of high building costs.

The sale is considered a pretty good one from the basis of creditors as the amount realized will allow the concern to pay creditors about thirty-three cents on the dollar. Recently a tire plant at New Castle was sold by the referee in bankruptcy and it paid the creditors only twenty cents on the dollar.

## GOODYEAR RUBBER IS SUED

BOSTON, July 11—Suits were entered in the Federal Court here to-day against the Goodyear Tire & Rubber Co. of Akron, Ohio, alleging infringement of patent rights in the manufacture of certain automobile tire treads. The treads are alleged to be copies of a wheel invented some years ago for use on street railways to break up snow and ice.

The plaintiffs are Catherine M. Moyglan, administratrix of the estate of John A. Casey of Newburyport, inventor of the street railway wheels, and Emil H. Daniels, of Tampa, Fla. The court is asked to restrain further production of the treads and to assess damages covering the past six years.

## INVENTS ROTARY VALVE ENGINE

NEW YORK, July 11—Eugene Bournonville, the head of the Bournonville Welding Co., one of the pioneers in the development of welding, has invented a rotary valve engine and has manufactured about half a dozen of these at a plant in Hoboken, N. J. It is understood that Bournonville will also manufacture a car in which this engine will be used and the car will be known as the Rotarian. The company will manufacture under the name of the Bournonville Rotary Valve Motor Co.

## Durant Gives Contract to Continental Motors

DETROIT, July 13—A contract for several thousand four cylinder engines for Durant Motors, Inc., has been placed with the Continental Motors Corp. Work on their construction will be started Aug. 1. The Continental plant now is being tooled for production of the motors which will be of a special type. The output will be increased steadily until it reaches 150 a day. The motors will be shipped to the Durant plant in Long Island City, the factory under construction at Oakland and the main plant in Lansing.

It is understood that negotiations have been virtually completed by Durant Motors for its supply of axles and frames although contracts have not been formally signed. The axles probably will be made in Detroit and the frames in Milwaukee.

## Plan Two Tractor Shows in the West This Winter

CHICAGO, July 12—Definite decision to hold a tractor show in Minneapolis, Jan. 30 to Feb. 4, inclusive, and to hold a show week in Kansas City during the winter, was made by the national demonstration and show committee of the National Implement & Vehicle Association at a meeting here to-day. The Kansas City event will not be held in any central building but each manufacturer will convert his Kansas City headquarters into a display room with general co-operation in publicity and other features to attract visitors into the city from the Mid-West agricultural territory.

## URGE A. E. F. TRUCK PROTEST

NEW YORK, July 11.—The National Automobile Chamber of Commerce has requested members to communicate with the House Ways and Means Committee at Washington, urging approval of the Graham resolution. The resolution imposes a 300 per cent duty upon reimported material originally designed for use by American Expeditionary Forces.

## Value of Automotive Statistics Is in Proper Analysis

An industry as new as that of automotive transportation has not defined its position precisely, hence its figures can be used intelligently only by a proper understanding of the factors affecting them.

By Clyde Jennings

**F**IGURES in the hands of the amateur statistician, or the non-statistician who does not inject an understanding of all factors into their application, are about as dangerous to the business world as high explosive bombs would be to an army if intrusted to inexperienced air pilots. The fact that torpedoes used for signals in railway traffic are constantly collecting a harvest of boys' fingers, does not lessen the fact that these torpedoes are extremely useful as railway danger signals.

These remarks are called forth by the current use of certain alleged automotive figures to prove various things.

The fact that automotive statistics are used as proving conclusively, without a due regard to other factors, the future trend of the business is a considerable indictment of the persons who so use them.

Automotive figures, when correctly interpreted, are a valuable guide for the future, but when used alone, without a due consideration of the daily shifting conditions, they are especially confusing. No capable student of the automotive industry to-day will contend that the percentage of development of the last years will be continued. Neither will this same student admit that the industry is near its peak of development. These conclusions are obtained by studying the automotive vehicle in connection with the peo-

ple who use it. No study of the industry can be worth while that does not place facts as they exist above the theory of a few years ago.

It is more than passing strange that one of the favorite amusements of statisticians is (and has been for several years) a study of the saturation point of automotive vehicles. The writer has been a publicist for a number of years, but he does not recall ever having read a serious article on the saturation point of any other sort of transportation—which includes railroad cars, horses, mules, baby carriages and some other equipment.

When railroad cars are idle the answer is that business is below normal. When motor trucks are idle the answer is that there are too many trucks. No one apparently concerns himself as to why horses, mules and baby carriages are idle. The proper answer is, of course, that the truck being a freight vehicle will be active or idle just as there is freight to haul. Early last year there was an immense quantity of freight to be moved and all trucks were at work and there was an active buying of trucks. A freight slump came on, some trucks went idle and the buying demand fell off. This demand will come back when freight movement comes back to normal.

Now a few words about the passenger car. A good many people have been worrying themselves because

there are more passenger cars in use than there are families of more than \$2000 incomes, as shown by some ancient income tax records. A reason for this worry is shown by listing the average expenditure of the theoretical family, which leaves no place for the support of a motor car.

There are two obvious errors in this reasoning, both of which any man can prove by mentally reviewing facts with which he is familiar.

First: Income tax records are not and never have been an accurate guide to the available incomes of the families of this country. It is a very well-known fact that few farmers are listed in income taxes, while they live in circumstances quite comparable with the city man who is listed at \$5000 a year. A farmer may handle actually less than \$1000 a year and still be quite well off and have more money for personal expenses than a man who is well up in income, but without other sources of income. Income is a very poor measure of buying ability, unless one knows well the ability of the buyer, and what is behind the income. All of us know well families that practically live off of a flock of chickens, or off of a garden that the family cultivates as recreation, and which find no way into an income tax return. Also each of us knows some housewife who buys twice as much with the family income as another housewife. Some families are poor on a \$2000 income, while others ride in motor cars and go to picture shows.

So far as we have been able to find in reading several hundred articles on the saturation point, no one has ever taken these facts into consideration.

#### Incomes Earned by Use of Cars

Second: In the estimate of an arbitrary figure that governs the ownership of a motor vehicle, we have never seen the point made that a good many men whose income is rated at \$1200 or thereabouts, earn this income because they are the possessors of a motor vehicle. Is any one of these amateur statisticians prepared to say how many second-hand motor cars, sold for something like \$300 each, have been turned into taxicabs and jitneys and are earning a living solely because they own this vehicle?

There is in New York a family that recently was comparatively wealthy. After the crash a high powered, expensive motor car was the sole possession, aside from household furniture. But the housewife was a resourceful woman. She has not only been supporting the family but has accumulated some savings from the operation of this vehicle at good prices for well-to-do visitors in the city.

Again, corporations are seldom counted when it comes to the ownership of motor vehicles, and yet some of them own thousands of the kinds of vehicles that are not usually thought of in this connection. Think, for a moment, of the low-priced roadsters that are owned by corporations and which are operated daily by men who do not come into the high ranking income class.

Another instance of error: The Delaware registration list reveals that one man in that State caused to be registered at one time 11 motor vehicles. Later some others were registered. These vehicles were for use of his family and for the business of his estate. This man also has at least two cars registered in New York. All of these vehicles are for the individual use of himself and his family.

A few years ago one of the favorite arguments for a limitation of the ownership of motor vehicles was that the farmer would have nothing to do with them. The amateur statistician apparently has not yet realized the extent of farm ownership, which is not in the slightest

comparable with income taxes. A farm hand, who is given house rent, a garden plot, the use of a cow and a few other favors by his employer in addition to his \$50 a month, is a very legitimate motor car owner, if he patronizes the used car market, keeps down the initial investment and does his own repairing.

Recently there has been an epidemic of depreciation figures—most of which are entirely out of reason. The source of these was apparently with the railway statisticians who are well able to average depreciation of their own products. The circumstances are entirely different. All railroad equipment is handled by hired men and under given conditions. Its ownership is a matter of accurate record. The workmanship involved in the building is about the same. There is a condition easily averaged under the long period covered by railroad equipment since it has been fairly representative of the population.

But with motor cars it is different. The source of supply is vastly different and the workmanship is different. Also the various vehicles are not always used for the purpose for which they were intended and the conditions under which they are used is as different as the condition of the several highways over which they are used, plus the handicap of the ability and temper of the driver.

The real facts concerning the depreciation is that it is not an average in keeping with the life of the vehicle. Here, again, figures have been used without understanding. It is true that mathematics have shown that the life of a vehicle is 5.3 years with the figures now available. One difficulty with these figures is that they do not cover a long enough period. Even approximate figures on national registration are not available before 1912 and those of us who have had to do with the compilation of registration figures know how faulty these figures are. That these figures are inadequate every person who has had to do with them knows perfectly well. They are probably more, much more in error, than the production figures. Here is an instance which shows that some knowledge is required to properly use these figures:

#### Orphan Cars in Kansas

The recent statement of the Secretary of State of Kansas shows that there were in that State during the last registration year more than 1000 cars which were orphans in 1913 at the latest. In other words, the factories which made these cars quit operations in 1913. Also there are in Kansas 200 cars which have no manufacturer. These cars were built by mechanics for their own amusement and their own use of parts of wrecked cars and parts from other sources.

Recently a banker's statistical company estimated that there were 500,000 motor vehicles in this country that were not registered in any State. This figure may sound surprisingly large, but the more attention that is paid to this feature, the more the student is inclined to believe that the figure is quite conservative.

The effort is not made here to assert that automotive figures are not worth while. They are, decidedly so. The point is that they must be used with some understanding and the person who uses these figures must have a fair knowledge of the source of them before he uses them. Last fall some persons within the industry became quite excited over a pamphlet published by a weekly paper seeking automotive advertising as to the replacement market. The fact that this job of chart making was based on only part of the figures of the industry apparently made no difference as to its acceptance. Just why it was so widely accepted has never been explained. The

fact that the export figures were not mentioned in this pamphlet should have shown that it was made without thought or knowledge of the field.

Depreciation of automotive vehicles as a whole is a peculiar topic and when the final word is said there are many factors that will enter into the compilation.

First, there is such a great variety of vehicles, used in so many different ways that an average is very difficult without some intimate knowledge of the subject. The low figure for the average life of a vehicle is undoubtedly due to the hard use given to the light, low-priced vehicles, which probably are 50 per cent of the total registration. But should these be allowed to determine the depreciation for the entire industry? That is quite another question and one that must be carefully considered. Frankly, it would appear that an accurate average is almost impossible.

The state of mind of the users of the 9,000,000 vehicles is a factor to be considered in this connection. It would not be possible in railroad statistics to entirely cut out wreckage of equipment for one year. But that is what happened with the automotive industry in 1918. That year there were 8000 more vehicles at the end of the year than at the beginning with all of the production added. The observing student of the industry did not see anything extraordinary about this, as he was well aware of the vehicles in the used vehicle dealers' stocks and of the vehicles that are allowed to remain in shelter during an entire year without registration. When a season comes along that vehicles are in great

demand and new vehicles are not available, then a lot of these vehicles that had been set aside are brushed up, oiled and put into use. And be it said to the credit of the builders, that these ancient vehicles give excellent service when they are called upon.

The object of this effort is not to belittle such statistics of the automotive industry and of automotive vehicles as are available. It is merely an effort to prove that the person who interprets these statistics must be a person of understanding and that he must draw on his knowledge of the industry as well as the statistics available. There are well-defined sciences of probability and of correlation, by which it is possible to interpret statistics into working figures. This industry is new and overturning of regularity within the industry during the war has done much to make our figures extremely difficult to apply to regular business.

The growth of the industry, its wonderful industrial romance and its unparalleled success has made it a target for all manner of marksmen. Most of these marksmen have had not the slightest knowledge of their ammunition. This fact has been well known to the close students of the industry and they have been cautious about putting forth figures and especially conclusions. But where those who knew the industry best hesitated, those who knew the industry least have not feared to enter. The result is that there are reams and reams of statistical pages about our industry that, if they were only entertaining to the public, would do no harm, but they are read by many who accept them as meaning something.

## Axle Anchorage of Cantilever and Quarter-Elliptic Springs

A POINT worthy of consideration in connection with the anchorage on the rear axle of cantilever and quarter-elliptic springs occurs in the Bugatti light car, which is said to have extraordinary road-holding qualities. One feature of this car's suspension is the peculiar mounting of the quarter-elliptic springs on the frame. The thick ends are attached to the rear end of the frame while the thin ends project forward. The thin ends of the springs are attached to pivot pins mounted in front of the vertical center line of the axle as the accompanying sketch indicates. By this arrangement the rear weight of the chassis is imposed on the driving axle in such a manner as to balance, to a large extent, the driving torque.

When, as is usual practice, cantilever or quarter-elliptic springs are mounted immediately above or below the center of the axle, the road wheel, when it comes down to the ground after surmounting a bump, momentarily decelerates and reacts upon the driving axle, causing the

latter to turn backward slightly and "kick up" the front end of the torque tube. This in turn tends to lift the front end of the car, diminishes the load on the front axle springs, intensifies the rear axle load and sets down the rear springs so that these are trebly punished by load, impact and torque, all this occurring at a moment when the front springs are relieved and thus intensifying fore and aft pitching.

In the case of the Bugatti, when the wheel with its backward reaction on the axle comes down to earth, at that moment precisely the load also comes down on to the axle with its forward reaction. Thus one balances or tends to balance the other, with the result that the front end of the chassis is not lifted, the rear springs are not excessively flexed, rebound is less and pitching fore and aft does not occur.

The foregoing is, at all events, the explanation put forward by a critical user in England, and as already suggested the possibility of there being advantages worth having in the Bugatti arrangement makes it desirable that further experiments be made.

Spring mounting on Bugatti light car

THE use of cast iron blocks for road construction is advocated by a metallurgical concern in France which induced the Municipality of Lyons to reconstruct an experimental stretch of road with such blocks a year ago. The results are said to have been good under heavy traffic, and it is reported that the system would be largely adopted if it were not for the difficulty of providing the necessary funds. The surface is first prepared with a layer of concrete about 4 in. thick, on which is placed the same thickness of neat Portland cement, carefully leveled to receive the cast iron blocks. The blocks are laid with spaces between them, and they are bound together with concrete, which is carefully rammed in to combine with the cement bed before the latter sets.

# A New Form of Air Cleaner

Performance characteristics of the Stewart air washer; and a description of test methods and apparatus employed in the examination of this class of automotive apparatus under a wide range of conditions.

By P. S. Tice\*

**W**HILE the obvious prime function of an air cleaner is that it shall remove the greatest possible percentage of foreign matter from the air drawn through it, there are other important considerations involved in the design of this class of apparatus. Chief of these latter is that the cleaner shall cause a negligible throttling of the engine intake. A further important point, if the cleaner is a wet one (properly a washer), is that the consumption rates of the water shall be reasonably small.

It is somewhat outside the purpose of the present discussion to go extensively into the relative merits of wet and dry types of air cleaners. However, experimental evidence shows that: (1) A given high standard of cleaning efficiency is attainable with less intake throttling in the wet than in the dry type cleaner; (2) in the wet type cleaner, accumulation of dirt removed from the air neither increases the throttling of the engine nor reduces the cleaning efficiency of the washer, and (3) use of a wet type cleaner results in a valuable humidification and cooling of the air supplied the engine.

In the design of the Stewart air washer, shown in section in Fig. 1, it has been sought to combine the maximum in cleaning efficiency with negligible intake throttling and minimum water consumptions.

## Water Consumption and Cleaning Efficiency

When the study and development of air washers was undertaken it very early became apparent that the usual high rates of water consumption in wet type cleaners resulted from failure to remove entrained water globules from the air stream. Furthermore, such entrained liquid is charged with the materials it is sought to remove from the air; and, if liquid thus passes out

of the washer with the air, the purpose of the washer is defeated to just the extent that this water loss is permitted. For these reasons the washer design under discussion has been developed to a point where no entrained water globules pass out of the washer with the air stream. Realization of this condition conserves the water supply and contributes materially to the high cleaning efficiency attained.

Referring to Fig. 1 it is seen that the washer as a whole is divided by a partition into a reservoir chamber and a washing chamber. The former is provided with a large filler opening and has two points of communication with the washing chamber—a water passage by way of the spring-seated flap valve which forms a part of the drain fitting, and an air vent tube rising to a point above the level of the liquid in the reservoir chamber.

When the filler cap is removed the flap valve closes automatically and the reservoir can be charged with water. Upon screwing in the filler cap, the flap valve is opened and water flows into the washing chamber, fills the glass trapping jar and rises to a height which submerges the lower end of the vent tube mentioned above. The filler cap being seated air-tight upon its gasket, water stops flowing to the washing chamber when the lower end of this vent tube is sealed by the rise of liquid, and flow is resumed only upon loss of liquid from the washing chamber sufficient to break the liquid seal of the vent tube. The vent tube thus determines the height of liquid in the washing chamber and serves to maintain a substantially constant level in it.

## Water Spraying

Within the washing chamber is mounted a symmetrical air duct having two throats formed in it, both throats standing below the water level and each being provided with a set of water entrance holes or jets. The

Fig. 1—(left)—Sectional views of the new Stewart air washer showing paths followed by the washing water, and method of controlling the water level. Fig. 2—(right)—How the sheet of water looks as it runs down the washing chamber wall. This view resulted from a three-minute exposure, with air passing at the rate of 4200 cubic feet per hour

\*Engineer in charge of Carburetor Division, Stewart-Warner Speedometer Corporation.

Fig. 3—(left)—General view of the apparatus set-up used in determining the effects of atmospheric humidity and temperature upon performance of the washer. Fig. 4—(right)—The set-up for examining the cleaning efficiency, showing the special entrance duct with its dust dispensing chamber, and the drum containing the vacuum sweeper bag

air duct is so proportioned that the least pressure throughout the washer exists at the water jets, thus applying a head or pressure difference across the jets, just as in a carbureter. This effective head is, of course, augmented by the gravity head due to the height at which liquid stands in the chamber above the jet holes in the air duct wall.

Air being drawn through the duct encounters sheets of water spray in the duct throats, establishing very intimate contact between water and air, with the result that foreign materials in the air stream become wetted and are taken into suspension in the water.

As the air charged with water spray leaves the common vertical member of the air duct, it encounters a deflector plate so formed and mounted with relation to the duct that all the water globules are forced into contact with the concave surfaces of the deflector. It will be noted that the end walls of the washing chamber engage tangentially with the discharging edges of the deflector. For this reason, the film of water established on the deflector remains unbroken and passes down the end walls in continuous smooth sheets, without splashing, and with none of it again becoming entrained. The photographic view in Fig. 2, of a washer with a celluloid end wall, shows very clearly the nature of the water flow on these walls. This view was made with an air flow rate of 4200 cu. ft. of free air per hour.

#### Circulation of Water

Water returned to the bottom of the washing chamber from the deflector carries with it the dirt, which settles out into the trapping jar, from which it can be removed as required. The washing chamber water is continuously recirculated as above, bringing the dirt down with it; and the water lost by evaporation is made up by fresh water admitted from the reservoir as required.

To drain the whole washer, the drain cock is opened with the filler cap in place. If one desires to clean the trapping jar without losing the contents of the reservoir, the filler cap is removed, thus closing the flap valve between the two chambers. Opening of the drain cock then permits only the contents of the washing chamber to run out, down to the level of the end of the tube extending into the trapping jar, as seen in Fig. 1. The jar can then be removed without spilling any of the dirty water.

A very complete experimental examination has been

made of this air washer, for the purpose of determining its cleaning efficiencies and pressure losses at various rates of air flow, its rates of water consumption with respect to temperature and humidity of the atmosphere and its effects upon the humidities and temperatures of the air delivered to the engine under various atmospheric conditions.

The apparatus used in this work included an orifice type air meter, and electric heater for controlling the temperature of the air entering the washer, a humidifier for controlling the water vapor content of the air entering the washer, a trap for removing from the air stream any water globules carried from the humidifier in entrainment, special passages soldered to the air intakes of the washer with provisions for wet and dry thermocouples and a large glass chamber interposed between the washer and the engine. The last mentioned chamber was made of glass so that should any water be carried over from the washer, it could be instantly detected. This glass chamber also contained wet and dry thermocouples for determining the humidity and temperature of the air leaving the washer. A Leeds and Northrup potentiometer indicator and a Hinkley 4.00 x 5.25 x 4-cylinder engine completed the set-up, as shown in Fig. 3.

For determining the cleaning efficiency of the washer, a dust-dispensing member was attached to the washer entrance. This portion of the apparatus, shown in Fig. 4, consisted of a horizontal passage through which the air was drawn into the washer. Secured to its under side and opening into it, was a chamber having a steep conical bottom, into the apex of which a small stream of compressed air could be introduced. A quantity of dust placed in this lower chamber could thus be dispensed into the air stream in a thoroughly distributed state, and at any rate desired. A large size Hoover vacuum sweeper bag, which had been proven to have a dust-retaining efficiency of 100 per cent under the conditions of the tests, was mounted in a large galvanized iron drum, and was interposed between the washer and the engine intake with connections so made that the air from the washer passed from the interior of the bag into the drum and thence to the engine.

Observations of the following quantities were made in each run:

- A—air weight in lbs. per sec.,
- t—temp. deg. Fahr. of air at air meter,
- H—barometric height, mm. Hg.,

Fig. 5—The variations in outlet humidity, temperature drop and pressure loss, with change in the rate of air flow through the washer. Fig. 6—Effects upon water consumption, temperature drop and outlet humidity, of change in atmospheric humidity at the washer entrance

DB<sub>1</sub>—dry bulb at washer entrance,

DB<sub>2</sub>—dry bulb at washer exit,

WB<sub>1</sub>—wet bulb at washer entrance,

WB<sub>2</sub>—wet bulb at washer exit,

t<sub>w</sub>—temp. deg. Fahr. of water in washing chamber, and

h—pressure drop through washer in inches of water.

From these quantities were computed the relative humidities, water consumptions and temperature drops shown graphically in the curves.

### Method of Conducting Tests

In all of the test runs observations were recorded only after all temperatures had remained constant for one minute or longer. Three groups of runs were made:

(1) With temperature and humidity of entering air at constant values, and with the quantity of air varied, to determine the relationships between quantity of air aspirated and changes in humidification, pressure drop and temperature drops in both air and washing water.

(2) With the weight of air and its temperature at the washer entrance at constant values and its humidity varied through wide limits, to determine the effects of the humidity at the washer entrance upon outlet humidity, water consumption and temperature drops in both the air and washing water.

(3) With the weight of air and its humidity at the washer entrance at constant values and its temperature varied through wide limits, to determine the effects of temperature at the washer entrance upon outlet humidity, washer consumption and temperature drops in both air and washing water.

A fourth set of runs was made, in which, at each of

several air flow rates, the cleaning efficiency was found by dispensing a known weight of dust into the air stream entering the washer and comparing with these quantities the weights of dust passing the washer. Any dust passing the washer was caught in the sweeper bag discussed above; and its weight was determined by careful weighings of the bag before and after a run, the differences between these weights being taken as the weights of dust that had passed the washer.

### Quantity of Air Varied

In the runs involving constant entering air temperature and humidity, with the weight of air varied, Fig. 5, it develops that the change in outlet humidity with change in air velocity is very small. This is also true of the temperature of the washing water, and of the temperature drop in the air stream. It can be argued from these curves that increased air velocity causes, in this washer, a very nearly sufficiently finer division of the liquid to counterbalance the effect of reduced duration of contact between the air and water. The entering temperature and humidity selected and maintained in this group of runs (80 deg. Fahr., and 36 per cent) approximately represent average summer conditions in the Middle Western States.

The pressure drops through the washer are seen to be relatively very small, considering the intimacy of contact established with the water and the high values of the cleaning efficiency, as shown in Fig. 8.

In none of the runs here reported was it possible to detect the carrying out of water from the washer, in entrainment in the air stream. As a matter of fact, except for the sheets of water running down the end walls of the washing chamber from the deflector, the interior walls of this chamber remained absolutely dry under all conditions.

### Entering Humidity Varied

Maintaining the entering air temperature at 80 deg. Fahr., as before, and operating at about the maximum quantity of air, the entering humidity was varied from 18 per cent to 72 per cent, Fig. 6, with the result that the humidity at the washer outlet is shown to vary directly with that at the entrance. The temperature drop in the air stream varies, of course, inversely with the entering humidity, at a constant entering air temperature. The water consumptions found are represented wholly by the amounts evaporated, since none was carried over in entrainment. The water consumption rates found are comparatively very low, considering average wet cleaner practice, in spite of the much greater humidifications accomplished in this washer.

### Entering Temperature Varied

Operating with the same air quantity as before, and with an entering humidity of 40 per cent, the temperature of the entering air was varied from 72 deg. to 108 deg. Fahr., Fig. 7. In these runs both the temperature of the washing water and the temperature drop in the air stream are shown to be direct functions of the entering air temperature; while the curve of outlet humidity at first rises sharply, but rapidly flattens out. The water consumption curve is very interesting, as showing what really low values may be expected in service, under average conditions with respect to entering humidity. At the entrance temperature of 80 deg. Fahr. the consumption is .40 lb. per hr., at an air rate of 3200 cu. ft. per hr., corresponding to open throttle at about 1100 r.p.m. of the engine used. With a water reservoir capacity in the washer of one gallon (that employed in this

size of washer), it is seen that continuous operation for approximately 20 hours will be secured on one filling of the reservoir.

In the determinations of the cleaning efficiencies only the lightest and most difficult removable materials were employed. These were flour dust, thoroughly distributed in the entering air by the means discussed under the heading "Apparatus," and the finer of the sweepings from one of a new cement floor. This latter material is largely made up of extremely impalpable particles which remain in suspension in still air for great lengths of time.

In Fig. 8, showing the cleaning efficiency curve, it is stated that the average rate of dust supply was .858 lb. per hour. This is true, as an average for all four runs. But that point at an air rate of 2840 cu. ft. per hr. resulted from a rate of dust supply of 1.86 lb. per hr., which is enormously in excess of any service rate. The points of particular interest in this plotting are the high average cleaning efficiency, the small variations in cleaning efficiency with wide changes in the air flow rate, and the negligible effect upon cleaning efficiency of wide variations in the rate of dust supply.

The data here presented shows that a minimum cleaning efficiency of 97 per cent can reasonably be expected in service, with an entirely reasonable water consumption, and with an almost negligible restriction of the engine intake. At the same time the humidification and cooling of the air in its passage through the washer constitute obvious advantages for heavy duty service.

A group of ten of these air washers has been in experimental operation on a fleet of Diamond T trucks engaged in cement road building in central Illinois; and over a period of sixty days use the mean dust removal per car per ten-hour day has been approximately 4.4

Fig. 7—How the temperature of the entering air affects water consumption, outlet humidity and temperature drop in the air stream through the washer. Fig. 8—Variation in cleaning efficiency with change in air flow rate, using very fine dust thoroughly distributed in the air stream entering the washer

cu. in., with a mean water consumption per car per day of somewhere between .5 and .6 gallon.

## Cushion Tire for Heavy Trucks

A NEW type of truck tire has been marketed by the Firestone Tire and Rubber Co. known as the Firestone Giant Cushion tire. The new design is a development of the small cushion tire and the giant single groove solid. It will be made in sizes suitable for all sizes of truck from  $\frac{3}{4}$  ton to  $7\frac{1}{2}$  tons. One advantage over plain

solids claimed is that the tire will stay livelier until it is worn out. This tends to lessen the power required to move the truck, and it also reduces the tendency of the edges of the tire to break off due to abuse by operators. The tire is designed in accordance with S.A.E. standards.

Bowen grease or oil gun for chassis lubrication

Firestone giant cushion tire

## A Pressure Lubricating System

A SYSTEM of chassis lubrication whereby either grease or oil may be forced to the bearings under high pressure has been evolved by the Bowen Products Corp. It comprises one grease or oil gun and three types of dust-proof connections—straight, 45 deg. and 90 deg. The elbow connections are made for greater convenience in applying the gun to bearings which would be more or less inaccessible with the straight connection. All three connections are made in a number of different threads, and adapters are furnished for use on spring bolt heads and other similar places. For places where the lubricant is apt to be thrown out by centrifugal force the connection is fitted with a ball check valve.

For convenience in lubricating, the connectors are made with revolving caps, which make it possible to operate from any position. These caps are fastened to the connection and are easily snapped open and closed with the tip of the gun. These caps cannot be lost, and their use obviates the need of cleaning the connections each time the gun is used.

Among the claims made for the system are that it can be operated with one hand, will handle all grades of oil and grease, is quick and convenient and cleans as well as lubricates.

# Brake Lining Tests at the Bureau of Standards

**Trials of numerous samples under a variety of conditions show a wide variation in coefficient of friction and other characteristics. Some linings prove far more durable than others under identical test conditions.**

**T**HE Bureau of Standards in co-operation with the Motor Transport Corps and the Society of Automotive Engineers has been engaged for several months in making tests of brake lining materials primarily with a view to developing a standard testing method which would enable purchasers and manufacturers of such linings to intelligently determine what specifications these linings should be required to meet.

A report on the work accomplished to date was recently made at a meeting held at the Bureau and attended by representatives of many of the prominent brake-lining manufacturers.

Director Stratton of the Bureau opened the meeting with a short address in which he assured those present of the desire of the Bureau to co-operate with manufacturers in just such work as has been done on brake linings. Dr. H. C. Dickinson, under whose direction the brake-lining tests are conducted, stated that the Bureau has been engaged since December, 1919, in brake-lining investigations intended to determine the best procedure for the series of tests originally proposed. The Bureau has completed a large portion of the program which it was decided at that time to follow.

Mr. Von Ammon, who has been in immediate charge of the work, then made a report from which the following is abstracted:

The primary tests were intended to determine the durability of the brake lining in two types of runs, the first in which the temperature of the brake drum is kept approximately constant by the use of cooling water and the second, a severe service test, in which the temperature of the drum is allowed to rise to equilibrium with constant power absorption. Means for determining the coefficient of friction under various conditions were also to be provided and certain other less important tests were to be made.

The testing apparatus adopted for the purpose was described in *AUTOMOTIVE INDUSTRIES* for April 7, 1921. The two brake-lining samples used in each test are 2 in. wide,  $\frac{1}{4}$  in. thick and 11 in. long, each covering 90 deg. of the circumference of the 14-in. steel drum employed. The samples are secured to the steel shoes by means of 8 tubular brass rivets. The samples furnished by the manufacturers included practically all linings now in the market as well as a number in course of experimental development.

## Coefficient of Friction

During the long time run with cooled drum the coefficient remains more nearly constant than in hot tests. The average values were near .40, in some as low as .30, while in a few samples only were the averages over .50. The extreme values were approximately .28 and .60.

During the severe service run, hot tests, there was in most cases a marked drop in the value of the co-

efficient resulting from evaporation and carbonizing of impregnating materials. This is followed by an increase in the coefficient which, during the remainder of the run, shows less variation. During the latter period the average coefficient for most linings was found to be from .45 to .50; a few linings showed an average value nearer .40, while others showed nearer .60. The extreme values found during short periods were .75 and .12, the lowest values being reached during the first part of a run as referred to above.

The influence of oil on the coefficient of friction was determined on the water-cooled drum. New samples saturated with oil, and with oil constantly supplied showed a coefficient between .10 and .20. After discontinuing the supply of oil the coefficient rose in 15 to 30 min. to values between .20 and .30 and were then steadily maintained.

## Durability Tests

A large number of tests with water-cooled drum were conducted with various drum speeds and various power inputs. In some cases the linings tended to cut the drum and steel particles became imbedded in the lining and added to the scoring. Even with low unit pressures metal was sometimes found imbedded in the lining after one to three hours' running. It was found that if conditions of load and speed are so chosen that no linings in commercial use gather metal the time required for a test will be inconveniently long or if shortened will result in so small a wear that the conditions of wear and change of coefficient of friction at the heart of the lining will not be sufficiently well shown.

In order to determine the best condition of speed and power absorption in the hot, or severe service test, a considerable number of trials were made at various speeds from 300 to 1000 r.p.m. with power inputs varying from 4 to 10 hp. The combination of 6 hp. and 600 r.p.m. promise to be the most satisfactory while limiting the test to a reasonable length of time. A majority of linings required a test period of between 3 and 7 hrs. The maximum run was 16 hrs. for an experimental lining.

In all severe service tests there is, very soon after the load is put on, more or less smoke and the impregnating materials evaporate or burn out to a varying extent. The condition of the drum at the conclusion of a run was always good, but in many cases there accumulates on the drum a coating of varying quality. With some linings this coating was smooth, with others rough, sometimes both at different times.

## Supplementary Tests

Tests for determining the oil and water absorption were made by submerging specimens of lining in the liquid. It was found that oil absorption amounted from 7 to 30 per cent by weight, and the water absorption from

4 to 27 per cent. It was found that the change in thickness resulting from absorption is too small to cause linings to drag under any normal condition of use.

Some linings show a tendency to stick when allowed to cool on a hot brake drum. With a few samples allowed to cool in this manner it was found necessary to apply from 0 to 36 ft. lb. to overcome the sticking, some rubber linings showing the higher values in these limited tests, while with the woven linings tested the dry carbonized impregnating material seem to form a coating which prevented sticking.

#### Discussion

Mr. Carson of the Johns-Manville Co., pointed out that in such composite materials as brake linings, consisting of asbestos, cotton, wire and impregnating compounds a uniform coefficient of friction cannot be expected in any case. The coefficient is certain to vary as wear exposes

new layers. The more homogeneous the material is the more uniform the coefficient will be. Neither maximum nor minimum should be taken, but rather average values from the main portion of the run.

He was strongly of the opinion that test conditions should be so chosen as to eliminate the picking up of metal in the cold test by reducing the power absorbed, while keeping speed the same as for the hot test.

It was agreed that the performance tests should form the foundation on which all specifications should be built. It was also felt that specifications should not prescribe in detail the amounts of various materials, such as asbestos, cotton, etc., entering into the make-up or methods of manufacture of the linings.

Mr. Burton offered continued co-operation of the Motor Transport Corps with the Bureau of Standards and the S. A. E. Standards Committee in developing specifications along these lines.

## Centrifugal Castings

**I**RON castings made in metal molds rotated at high speed while the casting is being poured and cools have been made for some time for piston rings and other engine parts. According to *Engineering*, London, the first patent covering the casting of materials under centrifugal pressure was taken out by Eckhart in 1809. Many efforts to establish the process on a manufacturing basis have met with failure.

Stokes Castings, Ltd. of Mansfield, England, are now producing such castings on a considerable scale, the average output for the last few months having been at the rate of 2000 castings a week. Most of the castings are for internal combustion engine work, mainly piston ring pots and cylinder liners. Satisfactory machining qualities are said to be obtained without annealing the castings. Factors determining the qualities of the castings are the mixture, pouring temperature, die temperature, speed, etc.

*Engineering* states that the quality of the castings obtained is a marked metallurgical advance over the material cast in sand molds or stationary chills, and graphite plates are practically eliminated. For piston ring castings made by the centrifugal process it is claimed that the dirt and slag inclusions inevitable with any sand casting process, are squeezed out by the centrifugal force. Another advantage claimed is that the rings cut from the pot are uniform throughout instead of varying in quality from end to end of the pot, as in the case of pots cast vertically in sand. A manufacturer of internal combustion engines using a cast iron liner only a few millimeters thick, who had a great many wasters when using sand castings for the liners, was able to avoid practically all wastage when using these centrifugal castings.

The casting machine is direct-driven from a variable speed electric motor through a flexible coupling and friction clutch. The floor space occupied is about 12 x 3 ft. and a weekly output of between 3000 and 4000 castings is obtained from six machines. No floor space is occupied by moulding boxes or sand-mixing appliances, and waste of material is largely eliminated owing to the absence of headers, risers, etc. The time taken to produce a 6-in. diameter drum, counting from the time of pouring into the receiver on the machine to time of taking out the completed casting, is something under a minute.

Stokes Castings have up to the present largely confined their research to the question of grey cast-iron, but interesting experiments have been made with some of the non-ferrous metals, and analysis showed the interesting effect of the centrifugal action in that the tin and lead of a

Fig. 1—Polished specimen of centrifugal casting. Unetched, magnified 50 diams, showing cellular distribution of graphite

Fig. 2—Polished specimen high-grade sand casting. Unetched, magnified 50 diams, showing cellular distribution in the form of flakes

lead bronze had tended to fly to the outside of the casting, the Brinell hardness figures reflecting the displacement. For the analysis used it was estimated that an ordinary sand casting would give tensile figures of not much over 12 tons to the square inch, with an elongation of, say, 9 per cent. The centrifugal casting shows as high as 20 tons to the square inch a very marked improvement.

**T**HE Paris Academy of Science has been informed by M. Guillaume, Director of the International Bureau of Weights and Measures, that the Japanese Parliament has passed a law making the adoption of the metric system obligatory in Japan. The metric system has been optional in Japan since 1893, when the decimal system was adopted side by side with the Japanese weights and measures. In China, the decimal system was adopted in 1906, and the metric system, adopted in 1913, should become obligatory in 1923. In Siam, the metric system has been obligatory since 1912. Thus the metric system has been adopted throughout the Far East, and in France it is thought that the decision of Japan will have a certain influence in Anglo-Saxon countries, since the opponents of the metric system in the United States, Great Britain and the Colonies have partly based their objections to it on the need of conserving the English way of reckoning in the East.

# Combustion Phenomena Revealed by Indicator Cards

A discussion of experiments showing the effect of mixture proportions, ignition timing, cylinder temperature, and electrode temperature on the character of combustion. Heated spark plug is believed to be the final agent in causing knocking in most present day automobile engines.

By Victor R. Gage\*

**R**ECENTLY there have been many investigations made, and hypotheses advanced concerning the process, or processes, of combustion inside of a gasoline engine cylinder. The phenomena called detonation, pinking, or knocking, especially, have received much attention. The results herewith presented were obtained in an endeavor to produce detonation in an ordinary gasoline engine, and although detonation was seldom obtained, still much interesting information was secured concerning the general processes of combustion. This information may be useful in supplying a few of the

\*Assistant professor of experimental engineering, Sibley College, Cornell University.

many fragments of evidence which are necessary in order to complete the story of combustion.

Knocking and detonation, as well as other combustion phenomena, are inseparably connected with the quality of the mixture, the time of ignition, the density and temperature of the gases, and many other factors, such as turbulence, stratification and dilution.

The cards shown in Figs. 1 and 2 serve to show the effects of varying mixture only (Fig. 1) and of ignition timing only (Fig. 2). These two figures present both pressure-volume and pressure-time diagrams\*\* for usual operating conditions and are similar to those obtained in the regular course of instruction in the Sibley College, Mechanical Laboratory, Cornell University.

For the other diagrams, Figs. 3, 4 and 5, the factors which were intentionally varied were temperature (Fig. 3) and ignition conditions (Figs. 4 and 5).

All of the cards were taken from a single cylinder, 6.55 x 9-in. gasoline engine, with compression ratio of 4.1 to 1. The general shape of the combustion chamber and spark plug location is shown in the accompanying schematic drawing, Fig. 7. The approximate valve timing of the engine is: Intake opens 20 deg. late, closes 30 deg. late; exhaust opens 20 deg. early, closes 10 deg. late. The engine speed was maintained at 350 r.p.m. by a hit-or-miss governor, so that every working cycle is made with the same throttle conditions. The air supply to the carburetor was unheated, being taken direct from the room at about 75 or 80 deg. Fahr., the gasoline being at the same temperature. The mixture had only a few inches to travel from the carburetor venturi to the intake valve, and in this passage it was neither cooled nor heated, except for the cooling effect of the vaporization of the gasoline. Commercial gasoline, "Socony" brand, was employed as a fuel, being supplied through a needle valve controlled opening located at the

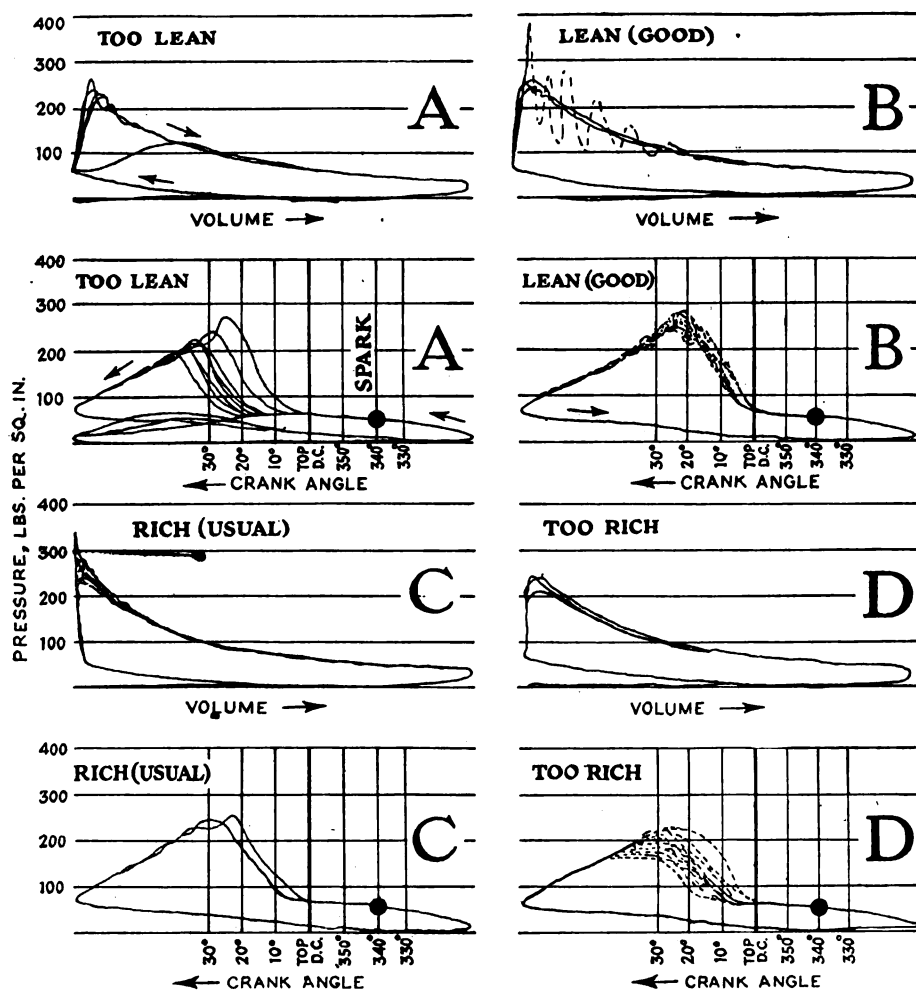

Fig. 1—Cards showing effect of varying mixture proportions

\*\*Similar cards were discussed by the author in "Effects of Varying Mixture and Ignition Timing" (Power, Nov. 23, 1915).

throat of an air venturi, just as in the usual straight tube carbureters.

The engine set-up is excellent for qualitative demonstration work, but it is not adapted to complete quantitative determinations. The load was applied by means of a band brake, and could be quickly changed to meet new conditions, such as a drop of power caused by lean mixture misfires. As the governor is a hit-or-miss type, the band brake is constantly regulated so as to seldom permit a "miss" stroke, but still allowing an occasional "miss" to make certain that the speed has not been reduced. The use of this combination, i.e., hit-or-miss governing and a quick acting brake secures: (1) constant speed, (2) constant throttle or manifold depression, and hence (3) a constant indicated load, as every power impulse is a full load explosion, and (4) the elimination of carbureter variables. In order to avoid any possibility of doubt, cards were not taken until two or three consecutive explosions followed a miss stroke, the only exception being in the case of an extremely lean mixture, when it is desired to obtain a card showing a backfire through the carbureter. As a matter of fact, one or two consecutive misses do not change engine conditions enough to make any perceptible change in the following explosion, except, perhaps, with an extremely lean mixture.

The indicator was suitable for a much higher speed than that employed on these tests, being a light weight inclosed spring Crosby Gas Engine Indicator, connected with the combustion chamber by a straight and large size opening. The corresponding pressure-time and pressure-volume cards were taken with the same engine conditions, but not at the same time. In taking cards the pencil was held on to the paper for many explosions, so as to secure a complete record of all fluctuations for a given set of operating conditions. In Figs. 1 and 2 it is seen that there is a complete cycle of fluctuation covering wide ranges of pressure with too lean or too rich mixtures, whereas all explosions are nearly alike when the mixture is correct. The ordinary pressure-volume indicator cards were taken in the usual manner, but special provisions were made to study the characteristics of the rise of pressure after ignition. In the latter case the eccentric which actuates the indicator is placed approximately 90 deg. out of phase with the crank, so that at the time of ignition when the engine piston is at the end of its stroke, the indicator card is in the middle of its movement. The engine flywheel was graduated in degrees, and a calibration or key card was made enabling the crank position to be superposed upon the misplaced diagrams. The result is that the central portion of these cards, where the combustion is located, is practically a pressure-time diagram, equal angles being nearly equally spaced, although at the ends of these diagrams this is not true. However, these cards will be spoken of as pressure-time diagrams. The time of ignition is shown by a dot on the compression line, located by means of the fly-wheel calibration and the key card.

The effect of change of mixture ratio with a fixed spark is shown on

Fig. 1, the usual pressure-volume cards (the upper card of each pair bearing the same letter) and the pressure-time cards (the lower card of each pair) are for the same conditions. The too lean mixture (cards A, Fig. 1) was the leanest at which the engine would run. It gives very erratic combustion. Sometimes the pressure does not rise at all, and it was at times necessary to choke the carbureter to prevent stalling. At other times, without having to strangle the carbureter, there would be a back-fire through the carbureter, which seemed to warm up the passages, so that the next time the spark passed a small pressure rise would occur, producing more heat and successively better pressure rises. The characteristic burning of this lean mixture seems to be that the spark properly ignites the charge, but that the heat generated by the burning charge is not sufficient. The lack of sufficient heat generation may result in a complete extinguishing of the combustion. It may result in a bare existence of the flame without any excess heat, so that the temperature of the mass does not rise, just as a piece of charcoal glows until the piece is entirely consumed. If this occurs it is quite probable that some portion of the charge is still burning when the intake valve opens, and so a back-fire will result. Or the charge may be ignited and burn in the regular manner, as shown by a few of the explosions which gave about 78 lb. indicated m.e.p.

For the next two cards (B and C, Fig. 1) the mixture was made slightly richer than the too lean condition, just enough richer to secure absolutely certain engine operation, with no back-fires or weak explosions, as was shown by the large number of pressure-time diagrams

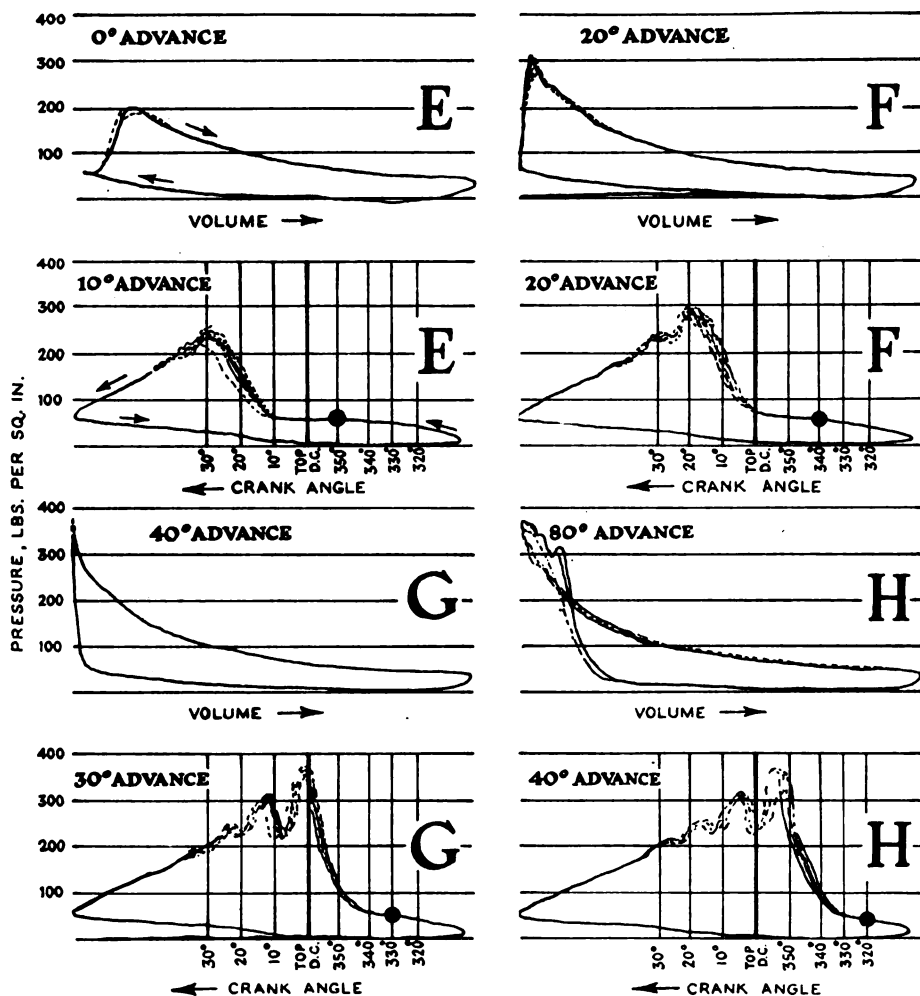

Fig. 2—Cards showing effect of ignition timing on combustion

Fig. 3—Cards showing the effect of heating the engine. Time of Ignition not varied

Fig. 5—Cards showing results of autog ignition brought about by plug shown in Fig. 6

which coincide. On the pressure-volume card one explosion (perhaps detonation) gave an exceedingly rapid rate of rise of pressure. This is shown by the excessive maximum pressure which was reached, and by the waves on the expansion line. A rapid rate of application of pressure upon the indicator piston acts just as a hammer blow, causing the parts to vibrate, whereas the usual (relatively) slow application of pressure acts simply as a gradual push upon the indicator piston. The action may be illustrated by the difference between pushing on a bar of iron, when no sound is produced, or tapping it with the same total pressure, but applying the pressure in a shorter time, when sound (vibration) is produced. In the optical type indicator, where the whole optical system is attached to the cylinder by an ell-shaped connection, the indicator waves may be produced by vibrations of the material of which the indicator is constructed, for example: in an inverted "L" one end of which is fastened rigidly to the engine cylinder, it is certain that engine vibration will cause the free end to move relatively to the fixed end. The richer mixtures never show appreciably indicator vibrations, because the rate of application of pressure is always relatively slow. Indicator vibrations increase with increase of the rate of application of pressure.

With the too rich mixtures the burning was always irregular, within limits, never refusing to burn and never burning very fast, as revealed by the several combustion lines of the last cards D of Fig. 1. The "rolling" of an automobile engine with a too rich mixture

is due to this characteristic as well as to manifold distribution.

The rate of rise of pressure is slowed up by richening the mixture. The slope of the combustion line on the pressure time cards indicates the rate of pressure rise; the steeper the line the faster the burning. The too lean mixture, cards A, Fig. 1, often gave as fast, if not a faster, rise of pressure than the good lean mixture (Cards B), and yet more spark advance is necessary with the too lean than with the good lean, because the too lean mixture hangs fire so long after the spark has passed and before the pressure rise begins, even though it burns, as fast or faster after it starts. The too rich mixture, cards D, also requires more spark advance than the good mixture, because it is slow burning throughout combustion period. Both too lean and too rich mixtures give less i.m.e.p. than a good mixture. With a too lean mixture, although the maximum pressure is sometimes greater than with a good mixture, the intermittent weak explosions will reduce the power output for a given time. With a too rich mixture the maximum pressure is always low and the after-burning does not cause the expansion line to fill out sufficiently to build up the m.e.p.

In connection with the relative meaning of too lean and good mixtures, cards A and B, it was noted that, with constant air and fuel temperatures, a mixture which was too lean at normal cylinder temperatures and spark advance was made to burn like

a good mixture with higher cylinder temperatures and with more spark advance. Most automobile engines have insufficient spark advance for a very lean mixture. The reason that a too lean mixture can be made normal by heating is perhaps explained by stating that the rate of combustion of a given mixture is controlled by its temperature and density at the time of ignition. If the temperature is increased, so is the rate of burning, because less heat is required to raise the mixture to its kindling temperature. If the density is greater (excluding liquid condition) the fuel and oxygen molecules are closer together and so unite more readily.

Density is proportional to the absolute pressure and inversely proportional to absolute temperature. Increasing the pressure at the time of ignition will increase the rate of combustion. This increase in pressure can be effected by an increase in temperature. But, in order to accomplish this the heating must be done after the intake valve is closed, when the cylinder is shut off from all outside passages, for under these conditions the volume will be constant and the pressure must rise with the temperature. If the temperature of the mixture is raised before the intake valve is closed the mixture will have a chance to expand back into the manifold or the air, and the volume occupied by a given weight will be increased, but no pressure change will occur. So it is possible to use a leaner mixture when the cylinder temperature and particularly the piston temperature is increased, or when a higher absolute pressure exists at the time of ignition, as with an increase of compres-

sion ratio. If a high compression engine is throttled this advantage is lost, because the absolute pressure at time of ignition is reduced. A change of spark timing either way from dead center causes ignition to occur at a lower pressure.

The foregoing statement that the rate and type of combustion is controlled by the temperature and density of the charge needs amplification. The total pressure was considered as a factor in the density. In strict truth, it is not the total pressure of the whole charge, but the partial pressure of the combustible elements which control the combustion. Knocking or detonation can be stopped by diluting the charge with inert gas, for example, by bleeding exhaust gas into the intake manifold. When this is done the total pressure at the end of compression is (hardly) changed, but, as the combustible elements are a smaller proportion of the contents of the cylinder, their partial pressures are much less than when the contents of the cylinder are not diluted with inert gases. Another factor affecting the pressure at the end of compression, but perhaps not a very big factor, is the heat taken up as latent heat when gasoline is vaporized during compression. The pressure at the end of compression will be higher with pure air than with a gasoline-air mixture and will be higher with a lean mixture than with a rich one, as more gasoline is vaporized when more is present, so both temperature and pressure at the end of compression are lower when richer mixtures are supplied. This explains at least in part the common practice of increasing the fuel supply when an automobile engine begins to knock.

The pressure rise shown on the indicator cards is closely connected with flame propagation, but the two are not identical. The pressure-time diagrams all indicate a time lag of about .007 to .01 sec. from the time of ignition until a perceptible indication of pressure rise due to combustion is recorded. Messrs. Woodbury, Lewis and Canfield\* have shown that this delay of pressure rise is an actual fact and of about the same order of magnitude shown on the cards here given. What the pressures are in the burnt gas, behind the flame front, is, of course, unknown, but it is believed that they are much greater than in the unburnt gas ahead of the flame front.

The diagrams of Fig. 2, cards E, F, G and H, illustrate the effects of altering the time of ignition. The maximum indicated m.e.p. is obtained from the engine if the pressure rise occurs when the piston has started on the expansion stroke, not when the piston is stationary at dead center. That such timing of pressure rise may give better thermodynamic efficiency is shown by W. S. Walker.\*\* The 80 deg. advance card (H) is similar to the card presented by S. W. Sparrow of the Bureau of Standards (S. A. E. Journal, October, 1920, page 397).

\*The Nature of Flame Movement in a Closed Cylinder, S. A. E. Journal, March, 1921, page 209.

\*\*Thermodynamic Cycles of Internal Combustion Engines, Engineering, London, Dec. 24, 1920, page 847.

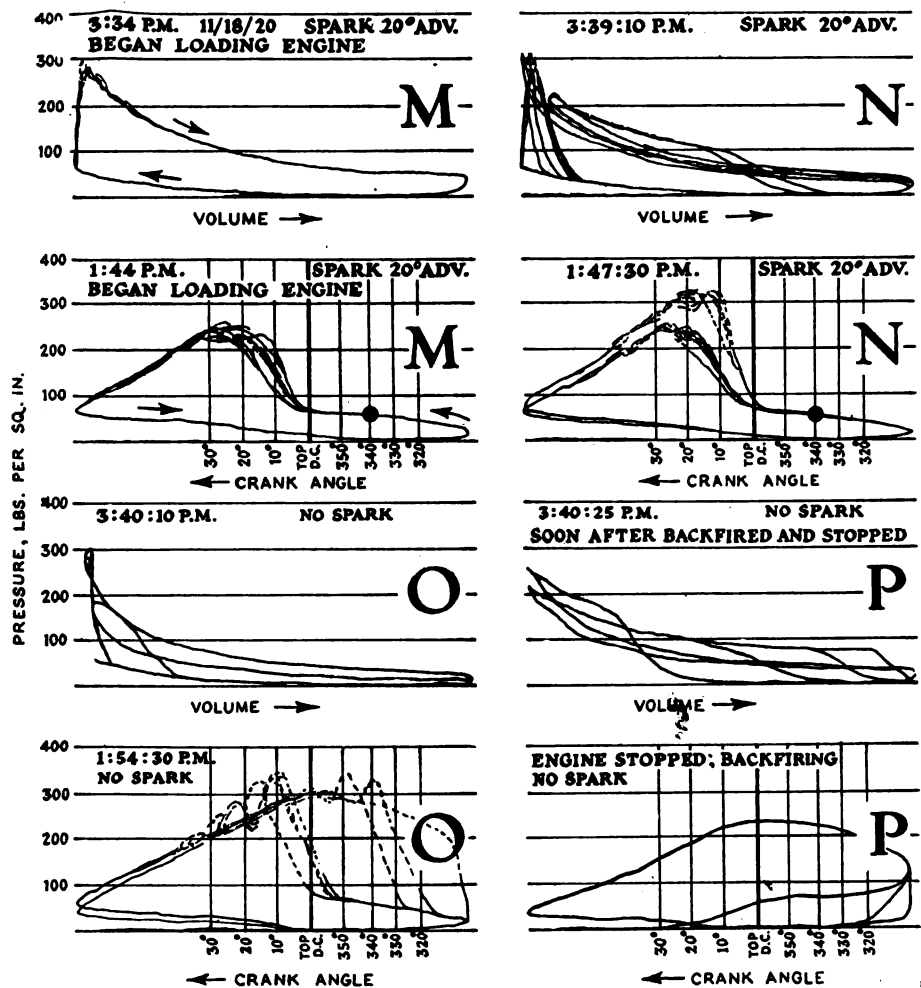

Fig. 4—Cards showing effect of heated spark plug electrode

The elapsed time between the starting of pressure rise and the maximum pressure is about .007 to .01 sec. Approximating the maximum distance which the flame has to travel from its source and approximating the time from the beginning to the end of pressure rise as shown on the pressure-time diagrams, where 10 deg. of crank travel are equal to nearly .005 sec., it is found that the rate of travel of the pressure wave is about 50 to 70 ft. per sec. If it be assumed that the time from the start to completion of pressure rise is a measure of the time of combustion, then the velocity of combustion will be approximately 50 to 70 ft. per sec. for conditions of normal burning. These values are comparable with the velocities of flame propagation given by Hohneman and McKenzie (S. A. E. Journal, November, 1919). When detonation takes place, the velocities indicated by the rapid pressure rise appear to produce practically spontaneous ignition throughout the mass, this occurring, however, after a short period of apparently normal combustion.

Fig. 3 presents a series of cards, I, J, K and L, taken to show the effects of heating the engine. Card L is the normal card obtained with best spark advance and with the mixture leaned as much as possible, but still obtaining regular firing. The cooling water was shut off immediately before this card was taken and the engine was run at practically full load, continuing for about nine minutes. Although the jacket was full of water at the start, much of it must have boiled away during the run, as the heat was sufficient to start cracking the paint on the engine cylinder. Cards were taken at three-minute intervals during the nine-minute period. These cards

show the changes in the process of combustion as the engine became hotter and hotter. The maximum pressure increased from normal of about 270 lb. per sq. in. to over 400 lb. per sq. in. The time of ignition was unchanged and the beginning of pressure rise (time lag from ignition) changes but little with engine temperature. But the location of maximum pressure shifts from 20 deg. after top center with cool engine to 10 deg. after center when very hot. Some of the highest pressures with the hot engine result from combustions which are nearly, if

Fig. 6 — Plug used in securing autoignition

not actually, detonations. There is not a preignition shown on any of the cards of Fig. 3, although the engine knocked badly while the cards, J, K and L, were being taken. In fact, the engine knocked badly with either preignitions, or rapid combustions, or detonations.

In order to obtain preignition a piece of a broken spark plug porcelain was placed around the center electrode of a good plug, the engine was run under nearly full load, but with the usual rather cold jacket water. Typical cards for these conditions, M, N, O and P, are reproduced in Fig. 4. In this figure even the first card of the pressure-time series, taken immediately upon application of the load, indicates erratic combustion. Card N shows two distinct types of combustion, neither of which is detonation. For card O there was no electric ignition and the several diagrams show combustions ranging from normal to a preignition occurring during the compression stroke, but without any detonations. On card P the ignition was occurring earlier and earlier until it caused ignition of the incoming charge during the suction stroke, resulting in several back-fires through the carbureter, and finally stopping the engine.

Reviewing the cards of Fig. 4, it is interesting to note that the maximum pressure and the whole expansion line of the quicker combustions on pressure-time card N are above the slower ones. On the cards O and P the too early combustion is shown to be complete, and the subsequent expansion of the compressed burnt gases follows the normal expansion, except for leakage and cooling losses. This phenomenon is noted on the card shown by Sparrow in which after the pressure rise due to the early ignition is complete, the subsequent compression follows parallel to, and slightly above, the expansion.

The author has tentatively classified three types of combustion, each of which appears to be distinct. One of these types of combustion is the normal, relatively slow burning, shown as the lower set of combustion lines on pressure-time diagram N of Fig. 4. Another type is the faster burning shown by the upper, higher pressure combustion lines of the same diagram. Neither of these two types of combustion gave evidence of pinking, although the faster burning type did cause knocking. The third type of combustion has been classified as detonation, and is shown by a practically vertical pres-

sure line on the pressure-time diagrams. Cards S and T of Fig. 5 show such instantaneous pressure rise and pinking was suspected, although the knocking was so bad that it was almost impossible to be sure of an extra pink. The combustion lines on card L, Fig. 3, seem to start out with the second (rapid) type of combustion, which eventually changes over into the detonation type near the end of the process, when high pressures are existing. Cards G and H, Fig. 2, with too early ignition, also exhibit this tendency. The pressure-volume diagram B of Fig. 1 shows one freak combustion which may have been a detonation, but so far it has not been possible to again secure this freak combustion under the same conditions of operation.

For the purpose of studying the temperature required for ignition a special form of hot wire ignition in which the igniting wire should also be a resistance thermometer in order to measure the ignition temperatures, was to have been employed, but it was not possible to use this in tests here recorded. A qualitative study was possible, however, by using some less effective form of pre-igniter than the broken porcelain. A spark plug was found which offered possibilities of being converted from a spark plug into a sort of hot tube. This plug is shown in Fig. 6. There was no electricity used for ignition in any of the cards, Q, R, S and T, of Fig. 5, all of them resulting from autoignition. It was found that the plug in its original form would run the engine after the igniting current was shut off. Card Q is the result of such operation. The plug in its original form never caused any preignition with normal spark, but it would become hot enough to give irregular ignitions after the electric spark was cut off, such as would have been produced by a spark timing of from 10 deg. retard to 10 deg. advance. For obtaining the next card, R, the plug was changed by drilling a small hole in each of the two bridges which connect the end plate to the shell of the plug, as shown by the dotted circle in Fig. 6, so that there was not so much metal to conduct the heat away from the end plate. This gave a more regular autoignition, producing cards corresponding to those obtained with a spark advance of about from 5 to 20 deg. For card S the heat conducting capacity of the bridges was again reduced so that

Fig. 7—Diagram of engine cylinder showing shape of combustion chamber and location of indicator

the plate would run hotter, and the timing of the auto-ignition was thus still further advanced. The character of the combustion was also changed to detonation, which in card T is so early as to be preignition as well as detonation. The engine knocked during the period when last two cards were taken.

The mere fact that a spark plug gives autoignition when the ignition is off does not necessarily mean that the charge is preigniting. The ordinary spark knock when climbing a hill or with a carbonized engine is probably due to the fact that the temperature of the gases inside the cylinder is relatively increased, a condition

which was simulated in obtaining the cards shown in Fig. 3; resulting in some portion of the spark plug becoming hotter and perhaps causing the auto-ignition to come earlier in the stroke, as in Fig. 5. It is seen that such knocking can be stopped or reduced by reducing cylinder temperatures or otherwise securing a cooler spark plug. For example, more gasoline cools the cylinder as it uses more heat for its evaporation, and a retarded spark will also reduce temperatures by reducing the pressure at time of ignition. It is interesting to note that point ignition with the broken porcelain (Fig. 4) produced only one "near detonation," while ignition from the larger hot surface, when hot enough (cards S and T of Fig. 5) produces consistently repeated detonation.

It is suggested that ordinary combustion may be roughly divided into three types: (1) normal, (2) rapid, (3) detonation, of which the last two will cause knocking. The first two types are well exemplified by pressure-time diagram M, Fig. 4. When the "normal" explosions occurred, as shown by the lower combustion and expansion lines of this card, the engine did not knock. But it did knock when the combustion caused the higher pressure lines. It is peculiar that the time lag from the jumping of igniting spark till the beginning of pressure rise

is practically the same for these two types of combustion.

Knocking can also be caused by too early ignition, irrespective of the type of combustion which follows, and preignition is followed by any one of the three types of combustion, or by a combination of any of the types. The experience of the author with this and other gasoline engines leads him to suspect that the spark plug is almost always the final agent in causing knocking, although the misbehavior of the plug is generally induced by some cause independent of the plug. The spark plug does not get too hot until the piston and cylinder temperatures are increased by some condition such as carbon deposits. The knocking can be stopped by cooling the plug. This statement is made, in spite of the fact that it is known that different fuels have different knocking characteristics, because it is believed that none of the automobile engines now built have too high a compression for the present day fuels (most of them have too low a compression for good thermal efficiency) provided suitable plugs, plug location and plug cooling are provided. The only drawback to proper cooling of the spark plugs is that sometimes so much oil gets by the pistons that the plugs have to run hot or they will rapidly foul.

## Tests of Rust-Proofing Processes and Materials

THE Engineering Division of the Air Service at McCook Field has been conducting a series of tests on the effectiveness of various rust preventatives, especially with regard to their applicability to aircraft parts. Test specimens of sheet steel of uniform composition were cut to uniform size, 4 by 6 in., carefully cleaned to remove all rust, and thoroughly coated with the material to be tested. These were exposed out of doors for varying lengths of

time. Periodic examinations were made to ascertain the time of the initial appearance of rust and the rate of corrosion progression. These values, plotted against the time in the accompanying chart, show how long each coating will keep the piece of steel from rusting.

As a result of the tests the conclusion is reached that there is no known method by which complete protection is afforded. At best, all coatings are only inhibitive agents. An examination of the accompanying chart will show that these coatings have marked variations in protective properties. It will be noted that the two pieces of steel coated with Corol compound and the two coated with exhaust pipe enamel corroded the least. The Corol compound samples rusted 15 to 25 per cent during 247 days' exposure and the exhaust pipe enamel sample rusted 15 to 20 per cent during 247 days. Zink plating held up better than any other coating, corroding less than 1 per cent during 300 days.

## Aeronautical Safety Code

A CONFERENCE was held recently in Washington to consider the development of an Aeronautical Safety Code, for which the Bureau of Standards and the Society of Automotive Engineers have been designated as the joint sponsors by the American Engineering Standards Committee. This conference was attended by representatives of the War, Navy and Post Office departments, the National Advisory Committee for Aeronautics, the National Safety Council, Manufacturers' Aircraft Association and the Insurance Underwriters, as well as representatives of the two sponsors and the American Engineering Standards Committee.

It was the sense of this conference that a safety code ought to be developed without delay and that a committee should at once be formed which would include representatives of all organizations interested in this subject as well as those which were present at the conference. Invitations have, consequently, been extended to other interested organizations.

# Special Features in Cylinder Block Production

Cylinder block department producing 171 blocks per day contains special machinery from which exceptional production results are being obtained. A clamping device for holding blocks against locating face during profiling operation is one of the interesting features discussed.

By J. Edward Schipper

**F**ROM the standpoint of completeness of modern machine tool equipment, there are probably no plants in the country which surpass that of the new engine factory at the Olds Motor Works. This concern is manufacturing its own engine for its small, eight-cylinder car. The engine plant is entirely new and is equipped throughout with the latest developments in special machinery for this work. Some of the machines are establishing new records for continuity of performance, and one of the great features of the work is the accuracy of manufacture, in spite of the use of high-speed production methods.

The cylinder blocks for the eight-cylinder motor are arranged and so designed that there is no difference between the left and right block; that is, a block may be put on either the left or right side of the crankcase and consequently the number of differently made parts for the engine is cut in two, as compared with eight-cylinder motors in which the left and right blocks differ. This result has been accomplished by establishing exact symmetry of design between the front and rear end water connections and, of course, exact similarity between both ends of the blocks in all other respects.

The present production rate averages about 19 blocks per hour per machine. The shop is on a 9-hr. day, giving 171 cylinder blocks per day, or a capacity of 85 engines. The average amount of metal cut from each cylinder block is 16 lb., as the rough casting weighs about 73½ lb. and the finished casting 57 lb. This gives a total of over 2700 lb. of metal cut per day in the cylinder block department. At the present time, with the plant operation being kept down to a maximum economy, one operator can, in a number of instances, take care of two or three machines. The result is that these cylinder blocks are being turned out at a labor cost which is astoundingly low, in spite of the fact that the operators are making good money on the job.

## Roughing and Finishing Operation on One Machine

The first rough machining operation is handled on an Ingersoll rotary miller. The cylinder blocks are all inspected at the foundry and gaged in the usual manner to check up the amount of material at all machine surfaces. The Ingersoll rotary miller not only takes off the rough cut, but also takes the finish cut off in the same machine. The cut is taken from the top and bottom faces of the block, the rough cut taking off 3/32 of an inch and the finish cut 1/32 of an inch. The locating for this work is handled from a button located at the top of the water jacket and two locating pin bosses on the bottom flange. The clamp on the jig shown in

Fig. 1, which illustrates both cuts taken on this operation, forces the block against the locating pin, sideways, and the endwise location is from the outside of Nos. 1 and 4 cylinder walls. One of the features of this big milling machine, which is practically in continuous operation, is its great rigidity. The machine holds six blocks at a time and the operator is loading the blocks on the machine at the opposite side from that illustrated in Fig. 1. The machine readily takes care of the schedule production of 19 per hr., and provides an accuracy in the finish cut which permits of a dimensional range from 7.750 to 7.752 in. That is, a total variation of .002 in. on the finish cut between the top and bottom faces of the cylinder.

## Reaming and Drilling in Second Operation

The same operator who handles the first operation takes care of the second operation on these blocks. The second machine is a Foote-Burt drill with twelve spindles. This machine drills the bottom flange and two dowel holes, reaming the latter to locate the cylinder on the crankcase. The machine really performs two operations in doing this, as the reamers replace the drills for the two dowel holes, as shown in Fig. 2. The two drills which are replaced by reamers may be noted by the Magic quick-detachable chucks. The work is located by a V-block between the two center cylinder barrels and by two stops on the core side or inside of the cylinder block located at the end cylinders. This machine has the same capacity as the first milling operation; that is, 19 per hour, and, while it keeps the operator busy to run both these machines, he can readily do so by properly timing his movements.

The two dowel holes which align the cylinder with the crankcase, the drilling and reaming of which were described under the second operation, are utilized for locating practically all of the machine work which follows on the cylinder block. They are used for locating the third operation, which is done on a Foote-Burt machine, consisting of rough boring the four cylinders simultaneously. In this rough boring operation about 1/8 in. is taken off the cylinder bore, leaving about 1/32 in. on a side for finishing. This machine is capable of 19 per hour, to time it with the machines which precede it.

Another Ingersoll rotary miller mills both ends of the cylinder block at the rate of 20 per hour. This machine, like the machine described in the first operation, takes both a rough and finish cut off each end. The parts milled are the water opening pads on each end, the two ends being similar, as described, so that a block may be put on either the left or right side of the crankcase. The

Fig. 1—Ingersoll continuous rotary miller which takes rough and finish cut from top and bottom face of block. Fig. 2—Foote-Burt multiple spindle drill with twelve spindles which mills bottom flange and drills and reams the two dowel holes for locating the crankcase on the cylinder block. These dowel holes are used for locating practically all of the machine work on the block. The dowel spindles may be noted by the Magic quick-detachable chuck used for changing over to the reamers for these holes. Fig. 3—Foote-Burt machine for rough boring cylinder block. This machine takes about  $\frac{1}{8}$  in. off the bore and operates at the rate of 20 blocks per hr. Fig. 4—Ingersoll rotary miller for milling both ends of the block. Miller has both rough and finish cutters. Fig. 5—Milwaukee 3B miller which mills the intake manifold flange on all cylinder blocks. Fig. 6—Milwaukee miller for milling eight bolt hole faces and spot facing two bolt hole faces on Olds blocks. Note location on these operations, which is from dowel holes in bottom of blocks, the work being secured by clamps in the water outlet hole

Fig. 8—Three-way Foote-Burt drill, drilling 35 holes simultaneously, taking care of all the bolt holes on the top and both ends of the cylinder block. Fig. 9—Three-way Foote-Burt drill, drilling on front and rear sides of block and on top. Fig. 10—Cincinnati 24-in. radial which chamfers the gas intake manifold passage, counterbores and faces water circulation hole. Fig. 11—One of the Foote-Burt machines which works on the valve stem guide holes. There are a battery of these, one operator taking care of five machines, handling 75 blocks an hr. Fig. 12—View of the battery of Foote-Burt drills which is handled by one operator working on the valve stem guide holes and the valve opening chambers

Fig. 13—Two-way Foote-Burt taper which taps three water circulating plug holes on the rear side of the block, the gas intake manifold flange cap screw hole and two valve inspection cover stud holes simultaneously. Fig. 14—Three-way Foote-Burt taper which taps 35 holes simultaneously in the Olds cylinder blocks. Fig. 15—Foote-Burt machine for semi-finish reaming the valve stem guide holes. Fig. 16—Garvin taper which finish taps all the bolt holes for the cylinder head and exhaust manifold studs. Fig. 17—Fixture used for water testing the cylinder blocks. The water test is given at 60 lb. hydraulic pressure. Fig. 18—Foote-Burt machine for giving the cylinder blocks a semi-finish ream. One man runs three of these machines, which reams four cylinders bores at a time and takes off .064 in. of metal, leaving .020 in. for finish

cylinders are located for this operation by the dowel holes on the crankcase flange, and the blocks are held rigidly against the locating plate by means of a clamp bracket fastened between the two end cylinders. This bracket, which is bolted into place, is clearly illustrated in Fig. 4, which shows this operation.

A Milwaukee 3-B miller mills the intake manifold flange. Location for this is by the dowel pins and the work is secured by clamps in the water outlets. This milling machine, which is provided with five milling cutters, is illustrated in Fig. 5. The machine is capable of handling from 20 to 25 blocks per hour. Another Milwaukee miller with a single cutter mills eight bolt hole faces and spot faces two bolt holes. This single cutter miller is shown in Fig. 6. The block is located in the same way from the dowels on the bottom flange and is held against the bottom dowel plate by means of clamps in the water opening end. The miller is stationary, the table moves carrying the work to the cutters.

The following operation is a very interesting profiling job handled by an Automatic Machinery Co. profiler. This tool profiles the valve inspection cover surface and the operation is located from the dowel holes in the usual way. The profiling operation is around three sides of a rectangle and two machines of similar nature, one handling the rough cut and the second the finish cut, are used. Originally, it was intended to finish on both machines, but in order to hold the limit to .001 in., which is required on the finish cutter, it was found much easier on the tools to take off a rough cut of 7/32 in. on one machine and then take a light finish cut on the second.

### The Profiling Operation

The profiling operation is shown in Fig. 7. As may be noticed on the illustration, the clamping scheme for holding the cylinder blocks against the locating face is the same as that employed on several other operations where the block is laid on its side for the work. This operation is extremely hard on any kind of a milling cutter, and this way of handling it is one of the most ingenious features in the entire shop. The Automatic machine which does this work is, of course, a special machine built for the operation, as are practically 100 per cent of the machines taking care of the manufacture of these cylinder blocks.

A three-way, 35-spindle Foote-Burt drill takes care of all the bolt holes on both ends of the blocks and the water circulation holes on the top of the cylinder. This machine also drills at the same time the bolt holes for the exhaust manifold on the top of the blocks and the cylinder head bolt holes. The block is located in an oven type of jig, this jig being so designed that the block is slid in on guides and then the dowel pins raised by manipulating the lever crank shown at the bottom left side of the jig. The operation is illustrated in Fig. 8, and is a particularly good example of three-way drilling on cylinder block work.

Another three-way Foote-Burt machine drills the Welch plug holes and counterbores them. These are on the rear side of the block. The same machine also drills three water circulation holes on the rear side and the water circulation holes in the head. It also takes care of the intake manifold bolt holes and the valve inspection cover plate bolt holes on the front side of the block. This gives a total of 19 holes drilled simultaneously.

The operation shown in Fig. 10 is on a Cincinnati 24-in. radial which chamfers the gas intake manifold passage and counterbores and faces the water circulation hole. This operation is handled in a tumbling jig and located from the dowel holes in the usual manner. The jig, of

course, is indexing, as shown in the illustration.

The Foote-Burt machine illustrated in Fig. 11 is an eight-spindle machine which counterbores the core holes for the valve stem guide holes. A similar type of machine, which is illustrated in Fig. 12, drills and counterbores the valve stem guide holes. This machine has two sets of spindles, the block being moved back and forward to bring it into position for each set. The jig, of course, is indexing for this work and operates upon guides. The location is from the dowel holes similar to the other operations of this nature. The same operator handles the drilling and counterboring on this and a previous machine, as well as the reaming operation on the guide holes and valve opening chambers. He also handles the machine shown in Fig. 12, which counterbores for the valve head, and the other Foote-Burt machine, which faces the valve spring seat. With this series of five Foote-Burt machines all handled by one operator, one man is capable of taking care of the operations described, or 75 blocks per hour.

### Few Hand Operations Required

Practically the only hand operation on the entire job is that of counterboring all of the cap screw studs and bolt holes in the block. This is done on an air drill. Following this there is a two-way Foote-Burt tapper, shown in Fig. 13, which taps three water circulation plug holes on the rear side of the cylinder block, the gas intake manifold flange cap screw holes and two valve inspection cover stud holes. The location of this work is from the dowel holes on the crankcase flange, as previously described.

For tapping the top and end holes there is a three-way Foote-Burt tapper with 35 spindles. This takes care of the holes on all except the bottom side of the cylinder, on which the dowel locating holes are again employed for positioning of the work. This operation is shown in Fig. 14.

Following the tapping of the holes on all three sides, as described, there is an assembly operation in which the valve guides and end cover plate are fitted, the water circulating holes are fitted with Welch plugs and pipe plugs are placed in the water circulation holes. The blocks are then given a semi-finish ream in the valve guide holes on a Foote-Burt machine and then the valve opening is finish reamed and the valve seat roughed out. The location for this work is done on the dowels, the jig being so arranged that the dowels are depressed while the block is put in position beneath the spindles. Quick-acting chucks allow for the replacement of spindles to take care of the different operations on this same machine.

In order to make certain that the bolt holes for the cylinder head are all exactly finished, these are given a finish tapping operation on a Garvin tapper. This operation is shown in Fig. 16. Following the tapping operation, the cylinder blocks are ready for the water test, this being handled on the fixture shown in Fig. 17. The water test is given under 60-lb. hydraulic pressure. This is sufficient to bring to light any defective blocks.

One man operates three Foote-Burt machines for semi-finish reaming the cylinder blocks. All four cylinder barrels are reamed simultaneously. On this reaming operation, which is shown in Fig. 18, .064 in. of metal is taken off. The location for the work is from the dowels on the bottom flange of the cylinder block. After this operation .020 in. of metal is left for finishing the cylinder bore. The cylinder bores are chamfered at the top and bottom on another Foote-Burt machine, as illustrated in Fig. 19. One man handles eight spindles similar to those shown in Fig. 20. This finish reaming operation

Fig. 19—Chamfering the top and bottom of cylinder barrel on a Foots-Burt machine. Fig. 20—Finish reaming the cylinder bores. One bore is reamed at a time on these machines, one operator taking care of eight spindles. Fig. 21—Rolling the cylinder bores to a finished surface. It requires 15 min. to a block to do this work. There is a taper of about 3 deg. on the rolls which is sufficient to run them through the blocks. This rolling operation puts a mirror finish on the cylinder block, slightly compressing the outer skin of the metal. Fig. 22—Baker single-spindle machine for chamfering the connecting rod clearance at the bottom of the cylinder barrel. Fig. 23—Finishing the valve seat by hand. Fig. 24—Grinding-in the valves on a special Foots-Burt valve grinding machine

takes out the .020 in. of metal left for finishing the cylinders and is held to a limit of plus or minus .001 in. The diameter allowed is 2.874 in. to 2.875 in.

The final finish on the cylinder bores is by rolling. This work is also done on single spindle machines, the rolling operation being done by a tool which resembles in some respects a roller bearing. The blocks are rolled to their finish surface, giving them an exceptionally smooth and mirror-like appearance. There is a slight taper of about 3 deg. on the rolls, which is sufficient to run them through the blocks and to give the desired feed. It takes about 15 min. to a block in handling this operation. Location is by the dowel holes in the usual way, with clamps on the top side of the blocks to hold it firmly against the bed plate on which the locating

dowels are placed. This rolling operation is shown in Fig. 21.

A Baker single-spindle machine chamfers the connecting rod clearance at the bottom of the cylinder barrel, as shown in Fig. 22. The valve seats are then finished by hand, as illustrated in Fig. 23, and the valve guide holes are finish reamed on an air drill. The valves are ground in on a Foote-Burt special valve grinding machine, which gives the peculiar compound motion necessary for valve grinding. This machine spins the valves backward and forward through the arc of a circle and then lifts them and replaces them on the seat in the same way as the hand valve grinding operation, which is familiar to everyone. This operation concludes the manufacturing operations on the cylinder block.

## Dealer Aids Make for Better Farm Power Merchandising

**A** FEW automobile manufacturers have sufficiently interested themselves in their dealers' merchandising methods to lay out model garage and salesroom plans and equipment. In the cases where this has been done, the dealers have usually been very glad to receive the suggestions and to act upon them insofar as possible. The manufacturer can be of very valuable assistance in this way because he places at the disposal of the dealer the work and abilities of trained engineering and service men.

Automobile merchandising, however, has reached a higher state of refinement and development than has tractor selling, and the tractor manufacturer who provides such service for his dealers has an even more fertile field in which to work.

Very complete plans for the layout and equipment of a power farmer dealer's store have been prepared by the Moline Plow Company and presented to their dealers. The plans are arranged to take care of a dealer handling a full Moline power line, and are designed to combine a maximum of efficiency and service potentialities with a minimum of expense.

A brief explanation accompanies the floor plan of the salesroom and service station. This description points out the reasons for the various features embodied in the layout. In addition to the floor plan, a complete list has been compiled of the machinery, tools and equipment which such a dealer should have. This equipment is listed and supplemented with charts and diagrams showing the advantages and necessities of the various units. A practical arrangement of the necessary machinery is shown by drawings and printed explanations.

A model tractor delivery truck has been designed for the power farming dealer, and drawings of this truck accompany the other material. In addition to the truck model, there is a specially designed service car which is also described by drawings.

Among other things that have been worked out by this manufacturer as an assistance to the dealer, is a stock record card and bin index especially designed for the power farming dealer; also a job card that is simple to fill out, but which constitutes an effective record.

A somewhat similar example of a farm power manufacturer recognizing the necessity for providing constructive aid to his dealers is an accounting system which has been worked out by the Avery Company for its dealers. This system is designed primarily to meet the needs of the dealer in tractors, threshers, farm implements, etc. The system is complete as regards records, but comparatively simple to operate and maintain. It will mean a distinct step in the direction of progress if this firm can "sell" the plan to a majority of its dealers.

It is not so much the details of these plans that are of interest, as the fact that tractor manufacturers are devoting such intensive effort to the development and refinement of the sales efforts of their dealers. Such dealer helps as this are bound to increase the effectiveness of the tractor and power farming salesmen and dealers and will go a long way toward bringing that industry, at least, out of the present general industrial slump. It is doubtful if many pages of "pep" talks could accomplish nearly as much as will this constructive effort.

## British Tire Innovations

**S**EVERAL important variations in the policy of the British Dunlop Tyre Company are announced, as follows:

A range of straight-sided tires will be made in sizes from 32 x 3½ in. upward, with a new pattern non-skid tread. These straight-sided tires will have a cord fabric and a rim with a quick-detachable flange. All inner tubes are to be molded to the exact shape of the tire and will be jointless, both circumferentially and diametrically. Schrader valves in two sizes will be standard, steel-studded tires are abolished and canvas-cased covers will eventually disappear. Facilities will be provided for converting beaded-edge tire rims (clincher pattern) to the straight-sided type. A new detachable wire wheel, held by four or more studs and nuts, will be manufactured.

Beaded-edge covers will continue to be made for replacement purposes, and this will probably be necessary for many years to come, in view of the fact that practically all cars, except those of American manufacture, now in use in Great Britain have beaded-edge tires.

Although it has been suggested in some quarters that the use of straight-sided tires will eliminate the detachable wheel, this is not the view of the Dunlop company, who consider that interchangeable and quick-detachable wheels are almost as necessary with straight-sided tires and quick-detachable flange wheels as with beaded-edge tires; at all events, it is considered that the vast majority or motorists object to changing covers and tubes by the roadside, no matter how easily they may be fitted, if only because of the need for a certain amount of skill and muscular effort and the use of a pump. Detachable rims are not favored as an alternative.

This move of the Dunlop company in introducing a range of straight-sided tires will doubtless be followed sooner or later by other British tire firms, and there is good reason for believing that most of the cars at the next Olympia Show will have this type of tire.

# The Trailer's Place in Transportation Merchandising

## Part I

The attitude of truck manufacturers toward the trailer has changed in recent years. The problem of marketing the trailer, however, is not yet solved. The trailer may aid truck sales as an auxiliary hauling unit. This article and another to follow discuss trailer merchandising.

By H. W. Perry\*

**W**HEN the motor truck members of the National Automobile Chamber of Commerce, at their annual meeting in June, adopted a recommendation that pintle hooks for drawing trailers be adopted as standard equipment for motor trucks, they took a step that was highly significant. It was evidence of an important change in the attitude of the truck manufacturers toward the trailer and indicative of their recognition that trailers are going to be used more and more with motor trucks.

A few years ago the leading truck companies were opposed to the use of trailers with their standard trucks, and about seven years ago the truck committee of the chamber put itself on record in a resolution opposing the use of trailers with standard trucks except under the most favorable conditions. Engineer members of the committee maintained that the hauling of a trailer slowed down the speed of the truck, increased the consumption of fuel due to running in low and intermediate gear, and caused additional wear of mechanism and tires, so that any gain in increased load hauled was offset by greater operating expense and depreciation. Experience up to that time, perhaps, justified these conclusions. Trucks were less efficient and sturdy then than now, and trailers had not even approached their present stage of development; moreover, the experience of users was exceedingly limited and did not furnish a sufficient basis for a conclusive finding. This early opposition persisted, however, up to very recently. It is still felt by some truck makers and by the large majority of truck dealers. The dealers' lack of interest in or active disparagement of trailers arise from different causes, which will be dealt with later.

As recently as eighteen months ago one of the largest trailer companies wrote to the chief engineers of the most prominent truck companies asking for a frank statement of their attitude toward trailers, and in each case

received a reply that was more or less antagonistic toward trailer transportation. During the past year, however, the same company has had letters from practically all of the larger and many smaller truck companies requesting descriptive literature, operating cost data and leaflets for salesmen's handbooks. It has been evident for some time that a marked change in sentiment toward the trailer was developing, and the recent action of the N. A. C. C. confirms this publicly.

### Growing Co-operation

A number of truck companies already attach pintle hooks as standard equipment on their regular models, and about a score build short wheelbase trucks as tractors for drawing semi-trailers and pole, pipe or logging trailers. From time to time a truck company goes to a trailer manufacturer for advice regarding the production of such a tractor model. In fact, a highly desirable and commendable spirit of co-operation is developing between these two branches of the industry. This is as it should be, because the truck

Short wheelbase tractor for semi-trailers, with permanent cab and dual rear tires

and the trailer are both necessary units in economical highway transport and are interdependent; the trailer is useless without the truck and the motor truck is unsuited to certain kinds of work and is uneconomical under some hauling conditions without the trailer.

Formerly the truck interests were inclined to look upon the trailer as a competitor, believing that every sale of a trailer killed the sale of an additional truck, just as the railroads were of opinion that motor trucking cut into their traffic revenue. But as the railroads are beginning to see that motor trucks, by developing industry and commerce, are increasing the volume of the more profitable long-haul traffic, so the truck makers, by study of the situation, find that the trailer adapts the truck to new uses, makes it more profitable or economical for users and actually helps to create more sales.

The present depressed condition of general business is no doubt a powerful factor in drawing the favorable

\*Recently General Manager of the Trailer Manufacturers' Association.

Hauling uptake for 7500 ton ship with truck and four-wheel trailer in Philadelphia

attention of the motor truck sales managers and transportation engineers to the possibilities of trailers in their various types. The necessity of doing business on a narrower margin of profit than for many years past compels reduction of expenses in every direction, including the cost of haulage. If, by an installation of trucks or tractors and a fleet of trailers, a municipality, a lumber company, a haulage contractor or other business can do its hauling cheaper than with horses, a sale can be created for both types of vehicles where there would be no sale for trucks alone. It happens frequently that trailer salesmen develop prospects for an installation of trailers and are asked to recommend a make of truck or tractor for drawing them. In such cases they usually call for the co-operation of some truck representative. In any event, they naturally try to turn the sale to some truck company that is not afraid to recommend the use of trailers with its trucks and that is willing to meet the customer and trailer man half way by furnishing a suitable trailer coupling and the proper gear reduction for the work. As one trailer sales manager puts it: "The attachment of a pintle hook hitch as standard equipment on the rear of the truck indicates to the buyer that that particular make of truck has drawbar pull and that the makers are selling TRANSPORTATION as well as motor trucks. The successful motor truck manufacturer is going to be the one who can convince the purchaser that his truck will pull a load, in addition to carrying one." Says another trailer man: "I believe I am justified in saying that from now on the truck manufacturer cannot sell trucks as easily and with as little consideration of cost of operation as he has in the past. In consequence, the trailer will justly be considered a necessary adjunct to the truck in order to make truck operation economical."

#### Special Haulage Problems

Trailer manufacturers have given more thought and study to special haulage problems than the truck manufacturers and their sales organizations. The trailer is, indeed, a specialized product developed in its several forms to meet unusual conditions that were not fully or satisfactorily met by the truck alone. The trailer sales manager and trailer engineer, therefore, have a broad understanding of highway transportation problems. They cannot entertain any prejudice against the truck and are

always glad to co-operate with truck transportation engineers by supplying information and advice or suggestions. "Co-operation between the transportation engineers of the truck manufacturers and trailer manufacturers has been very good for the last two or three years and is constantly improving," says the general manager of a trailer company. "We have always felt that the truck engineers have co-operated with us, and we, of course, have with them. The ultimate gratifying results will no doubt be tangible very soon. And what I have said in regard to truck engineers and trailer engineers applies without modification to the relation of truck factory and trailer factory sales managers. There is a good deal of room for improvement along the lines of co-operation, but the improvement of the present time over what we had about four years ago is of great importance. I am looking into the very near future with a great deal of encouragement, visualizing a condition in which truck factory sales managers, district managers and even truck distributors will seek very close co-operation of our experts, and in a good many cases their advice, before they sell a complete truck installation. This view may be somewhat optimistic, but it is my conviction that, were it not for the fact that business is practically at a standstill in any line of endeavor, a great deal of this expected co-operation would right now be existing and working to the advantage of the ultimate buyer, who, after all, is the fellow that spends the money and must be served properly."

#### Sales Agencies a Problem

It is an open question to-day just how the trailer is going to dovetail into the truck business and by whom and how it is going to be marketed. Neither the truck makers nor the trailer makers have reached a satisfactory conclusion. The trailer industry is passing through much the same experience as the truck industry did in its earlier development, when it was found exceedingly difficult to effect sales through passenger car dealers and when exclusive truck agencies were unprofitable because of the limited truck market. In some respects the trailer business is analogous to the truck body business, but in the matter of selling it has to be conducted more nearly along the lines of the truck business, and is even more difficult.

The natural outlet for trailers should be through the

established truck dealers, who have all the facilities for conducting the business and have a good understanding of motor haulage, wide acquaintance with truck users, an intimate knowledge of the hauling requirements in their territory, and should be able to grasp readily the essentials of trailer transportation. Most of the trailer companies started their distribution on his assumption, and a large majority of trailer dealers to-day are established dealers in trucks. It has been found, however, that the truck dealer does not, as a rule, become an enthusiastic trailer man. In fact, he is less interested than the truck manufacturer. He finds that the problem of trailer transportation requires more study than truck transportation and that trailers are harder to sell because the trailer idea has to be sold to a prospect before the vehicle itself can be sold. The list price of trailers is much lower than on trucks, and, even with the same discount, the commission to dealers is comparatively small, so the dealer naturally prefers to make truck sales. Usually he has a considerable investment tied up in trucks and is anxious to turn his money over. The successful truck dealer and salesman are inclined to regard the trailer with some disdain and at best handle it only as an incidental side line. It has secondary place in their thoughts and, instead of taking a broad view of highway transportation and endeavoring to sell the equipment best suited to each particular job, they concentrate on the sale of trucks even in cases where the buyer would be benefited more by an installation of trailers.

The distributor under whom the dealer and salesman work contracts with the truck manufacturer for a stipulated number of trucks, usually for a period of one year. When times are good he cannot get enough machines to fill the demand and adjusts his sales and operating force to the volume of business to which the manufacturer limits him. On the other hand, when a reaction sets in and plenty of trucks are available but are harder to sell—a condition that has prevailed for the last twelve months—the distributor and the dealers make every effort toward moving the whole number of trucks for which they have contracted; consequently, the selling force has no time to give any attention to trailer sales. In such a situation they recommend trucks to purchasers who they know would be better served by trailers, but their problem is to move the trucks, and that is what they are doing. To make a success of trailer sales the dealer should put a salesman on the job exclusively. The passenger car dealers did not make a success of truck sales until they created a separate department for trucks and put truck salesmen on the job. And the truck salesmen had to be developed; it took a long time to convert a passenger car salesman into a good truck salesman, and it was often found easier and better to draw men from other lines of salesmanship instead.

### Trailer Selling Difficulties

The policy of marketing trailers through truck dealers meets another important difficulty. When the agency for a line of trailers is given to a truck dealer, the dealers in other makes of trucks in the same territory are very loath to send a customer for their trucks to a competing truck dealer to buy a trailer. Consequently, they

actively discourage the idea of using a trailer and to this extent become trailer "knockers." The psychology is perfectly obvious. On the other hand, where trailers are handled independently by an exclusive trailer representative there is no such objection.

Changed business conditions that have been brought about in the last twelve months may alter the attitude of the dealer, who now finds that the market for trucks has been oversold in many directions and that most owners of a number of trucks have from 25 to 50 per cent of their machines standing idle. There is little chance of selling these owners more equipment until the volume of their business increases to the point where all the trucks are used to capacity. When such revival has occurred, it is almost certain that the owners will consider much more carefully than heretofore the initial investment and subsequent operating expenses of new equipment and will be very attentive to arguments in favor of trailers. The dealer or the manufacturer who can show how an installation of trucks or tractors and trailers will cut down the hauling cost will be most likely to get the new business and in many cases will be able to supplant whole fleets of old and inefficient trucks.

It is admitted in the trade that many trucks sold to date were badly sold; that they are not giving the best and most economical service because they are not suited to the kind of work they are doing. These will be the first to be replaced, and tractors with semi-trailers or pole, pipe or logging trailers will be substituted because they can handle double or triple the tonnage in one load, can haul material or objects of unusual length or awkward size and weight, or can save idle time during loading and unloading operations.

In other cases smaller power units and medium-sized, four-wheel trailers will displace trucks of 5 to 7½ tons' capacity because of legal restrictions against excessive weight and because the trailer will take care of occasional overloads, while the smaller truck can handle the normal work more cheaply than the large truck operated with 50 per cent capacity loads.

### Studying Transportation

Just now the field of sales possibilities has to be raked with a fine-toothed comb to find worth-while prospects. Then some very convincing facts must be presented to lead up to a sale. The most likely field of endeavor is among lines of business in which horses are still used largely and for which the motor truck is not well suited. These trades need painstaking study and analysis, which the truck dealer who has not made a thorough study of highway transportation in all its phases, and particularly of trailers, is hardly competent to make. In such cases the dealer calls on the truck factory for assistance and the factory transportation engineer is sent to make an investigation and recommendations as to the proper equipment for the work. If analysis indicates a need for trailers, a trailer man may be called on for co-operation before the sale is consummated. Thus the factory is necessarily closely tied up with many retail sales, even though it has a complete system of distribution through branches, distributors and dealers.

Tank truck hauling four-wheel tank trailer, used for oil distribution. Trailer can be uncoupled and left at service station to be emptied while truck goes on to next delivery point

# Demonstration Shows Tractors More Economical

The average cost per acre of preparing soil for sowing was 57.20 cents by horse outfits as against 16.72 cents for kerosene tractors—the best six tractors averaged 12.8 cents. Other results obtained are not very complete, while the oil consumption figures present special difficulties.

By David Beecroft

**O**FFICIAL results of the three-day tractor demonstration held at Fargo, N. D., June 28, 29 and 30, have been issued by the committee of the National Implement and Vehicle Association having the work in charge. The issuance of the report was delayed because the horse outfits which were competing with the tractors had not completed their work until some days after the tractors had finished theirs. The demonstration consisted of each tractor plowing and cultivating a 10-acre tract of land in the black, level, gumbo areas adjacent to Fargo, N. D. The temperature was very high, the thermometer registering over 100 deg. Fahr. during the day, which made it particularly hard on the twelve horse outfits, seven of which withdrew. Of the thirty-seven tractors that competed, one was disqualified due to breaking a gear.

The results are not very complete and show only the numbers of gallons of gasoline or kerosene needed in plowing and cultivating per acre, and also the time required to do the work. The figures are not given for individual tractors, but only averages for all tractors. There were thirty-six tractors that completed the demonstration, and of these twenty-five burned kerosene and eleven burned gasoline.

## Fuel Consumption

The average fuel consumption for the twenty-five that burned kerosene in plowing 10 acres each amounted to 3.01 gal. per acre. Kerosene was worth 11.8 cents per gallon at Fargo, so that the kerosene cost per acre was 35.518 cents. To this should be added gasoline which was used by them in starting. Approximately .12 gal. per acre of gasoline was used, which, at a cost of 23.1 cents per gallon, gives a cost per acre of 2.772 cents for gasoline. Adding this to the kerosene cost gives an average of 38.29 cents per acre for fuel for the twenty-five kerosene-burning tractors.

The cost figures for the eleven tractors which burned gasoline showed that they used 2.77 gal. per acre in plowing, which, at 23.1 cents per gallon, gave a total cost of 63.987 cents per acre. It will be noted that the average amount of gasoline was less than kerosene, but the cost of gasoline being approximately double that of kerosene made the cost per acre approximately double.

It must be borne in mind that these figures represent average fuel consumption of the twenty-five kerosene-burning tractors in one case, and the eleven gasoline-burning tractors in another case. Two other sets of averages were given in the report, as follows:

A—The average of all of the tractors constituting the

better half of the group, those that would be above the average figures already quoted.

B—The average of the six tractors giving the lowest fuel performance.

The figures for the A group show considerable improvement over the average of all the tractors, in that the best half averaged 2.87 gal., compared with 3.01 for the first. This gives a fuel cost per acre of 36.24 cents, as compared with 38.29 cents per acre in the general average.

When the B group is considered—that is, the fuel economy per acre of the six best performing tractors—greatly improved results are shown, the average kerosene fuel consumption being 2.51 gal. per acre, instead of 3.01 gal. per acre for the entire group. The fuel cost per acre plowing by the six best performers was 30.56 cents per acre, with kerosene used as a fuel and gasoline used for starting purposes.

The three averages summarized as follows:

	Cost per acre
No. 1—General average (kerosene).....	38.29 cents
No. 1—General average (gasoline).....	63.98 "
No. 2—Best half average.....	36.24 "
No. 3—Best six average.....	30.56 "

## Oil Consumption

Figures on lubricating oil consumption were given, but AUTOMOTIVE INDUSTRIES greatly doubts the value of such figures, due to the difficulty of getting figures on engine oil consumption that admit of comparison with engines where different lubricating systems are used. There is also the difficulty of accurately measuring oil consumption over such a short period, while the problem of crankcase dilution is a factor that should be considered in connection with lubrication consumption report.

After each tractor had plowed its 10 acres it was required to cultivate and seed by means of disk harrows, spike-tooth harrows, seed drills and in some cases other farm equipment. This work was done immediately after the plowing was completed and a record was kept of the fuel used and the length of time required. For the four divisions given above the cost figures for fuel are:

	Cost per acre
No. 1—General average (kerosene).....	16.92 cents
No. 1—General average (gasoline).....	29.56 "
No. 2—Best half average.....	16.11 "
No. 3—Best six average.....	12.60 "

This summary shows that the best six had a fuel consumption at least 25 per cent better than the average of the twenty-five in No. 1 classification using kerosene.

The committee in charge endeavored to give some report on the time required in doing the work, and the

figures were given out in the form of man-hours per acre, that being an effort to arrive at the man-cost plowing per acre as compared with plowing per acre by horses. In the four classifications the number of man-hours per acre are given in the following tabulation, and the man-cost per acre reckoned on a wage of 40 cents per hour is also given:

	Man-hours per acre, plowing	Man cost per acre, plowing, cents
No. 1—General average (kerosene) .....	.94	37.60
No. 1—General average (gasoline) .....	.95	38.00
No. 2—Best half average.....	.95	38.00
No. 3—Best six average.....	.84	33.60

On a basis of a 10-hour day this puts the workman's wages at \$4 per diem.

Owing to the information not being given out as to the number of plows drawn by the six best tractors in the No. 3 group, it is not possible to arrive at conclusions as to whether the six best were machines pulling three, four, six or eight plows. The only figures are averages.

The report gives some figures on the five horse outfits, each of which plowed and cultivated 10 acres. Unfortunately, the figures are not given separately for plowing and cultivating, so that no comparisons can be drawn with the tractor classifications. They show the amount of hay and oats needed by each horse outfit and the number of man-hours for plowing and for seeding.

The horse outfits required 2.64 man-hours per acre, which, at 40 cents per hour, gives \$1.056 man-cost per acre, as compared with 33.6 cents by the best six tractors.

The cost of preparing the soil for sowing the seed and seeding, as based on a man-hour record, and labor at 40 cents per hour, shows that the cost per man-hour for the six best tractors is 12.80 cents, as compared with 57.20 cents by horse. Each horse outfit consisted of six horses. The tabulation for the different classifications is:

	Man hours per acre	Cost per acre
No. 1—General average (kerosene) .....	.418	16.72 cents
No. 1—General average (gasoline) .....	.43	17.20 "
No. 2—Best half average.....	.42	16.80 "
No. 3—Best six average.....	.32	12.80 "
Horse Outfit average .....	1.43	57.20 "

## Removal of Glue Stains

ACCORDING to the Forest Products Laboratory, casein and vegetable glues containing caustic soda produce stains on certain kinds of wood, notably the oaks, maple, cherry, elm, ash, birch and beech. Some glues stain the wood more than others, and those that contain the most alkali are likely to be most injurious. The staining is due to the action of the alkali in the glue on the tannins and other constituents of the wood, whereby a substance related to ink is formed. No means have yet been found of preventing this chemical action. Precautions can be taken which will keep the discoloration from the finished surfaces.

The most trouble with glue stain in woodworking is caused by the penetration of the glue solution through thin face veneers. This seepage is very likely to occur if the veneer is less than 1/20 in. thick and somewhat porous. The consistency of a glue in part determines whether it will be squeezed through the wood or not. It is quite obvious that under similar conditions a thin glue will penetrate farther than a thick glue. For this reason the quantity of water that is added to a glue might be diminished and "fillers" added when staining is feared. The amount of pressure exerted by the panels in the press is also a factor, but it would not be advisable to reduce the pressure in order to check the flow of the glue.

If a panel is dried promptly, the caustic-soda solution will have difficulty in coming to the surface. Rapid drying can be brought about by removing the panels from the press as soon as it is safe to do so, and placing them on stickers. The amount of staining can also be decreased somewhat by placing a caul or some other flat object between adjacent panels in the press.

Casein and vegetable glue stains can be almost entirely removed by sponging the stained surface with an oxalic acid solution, prepared by dissolving one ounce of oxalic acid crystals in about twelve ounces of water. Still better results can sometimes be obtained by moistening the wood first with a sodium-sulphite solution made up in the same concentration as the oxalic acid. In this way very stubborn stains can be almost obliterated.

## Small Motorcycle Performance

THE Tourist Trophy races constitute the major motorcycle event of the year in Great Britain. The features necessary in a machine to win one of these races include acceleration, ease of control, efficient braking, reliability and, last of all, speed. There are two classes, Junior and Senior, and the races are run over a typical road course. The Junior machines are limited to 350 c.c. and the Seniors to 500 c.c.

This year the Senior race was won by a Junior 350 c.c. machine running in the Senior class. Commenting upon the significance of this result, the *Motorcycle* says editorially:

"Many consider that the 500 c.c. machine is at a disadvantage on such a tortuous course, and that the race is not won on sheer speed on the level, but upon corner work. Be that as it may, the winner was in no sense a reckless rider, and, possessed of a mount which held the road magnificently, he was able to prove what we suggested after last year's Senior race, viz., that the present limit of 500 c.c. might reasonably be cut down to 350 c.c., Junior machines to 250 c.c., and genuine lightweights to 200 c.c. without loss of speed.

"After all, as we have long argued, if we gain anything by the T. T. it is in efficiency from a given capacity, and instead of piling on weight to cope with the increased speed attainable, and producing heavy solo machines (some scaled over 300 lb.), the natural course seems to be gradually to continue the restriction of engine "c.c.," and so gain the advantage of greater engine efficiency by reducing weight. Many question whether the ideal solo mount is a machine of 80-m.p.h. caliber scaling 300 lb.; yet that was a fairly common specification of Senior machines. Speed is only of real value when opportunities for its employment are available."

Fordson tractor equipped with pneumatic tires used for hauling various equipment at one of the plants of the U. S. Rubber Co.

# The Value of Foreign Trade as Hoover Sees It

In times when production capacity is greater than domestic needs, export sales should be measured by the buying power so given to those persons employed to produce these goods. Some workers are probably saved from poverty. Automotive export notes.

**S**OME highly interesting remarks on the general subject of export trade are found in an address by Herbert Hoover, Secretary of Commerce, at the National Shoe and Leather Exposition and Style Show at Boston. A few paragraphs from this address are quoted here:

There is a feeling of some uneasiness and even of pessimism regarding the future of our foreign trade in which I do not participate.

Our exports and imports during the last few months have dropped nearly 50 per cent in value from the high-water mark of a year ago. Some of this decrease is due to the fall in prices relatively more than volume; some of it to the temporary world depression, and some of it lies deeper.

In these times of troubled minds we find much conflict of opinion as to the situation and its remedies. Some extreme groups insist that inasmuch as our exports comprise but 10 per cent of our total production, therefore our foreign trade bears only this ratio to our economic life, and that consequently our true course is to forget it and to devote ourselves to healing our internal economic wounds. Other extreme groups consider that for our internal situation the only remedy is restoration of our export trade and they would undertake desperate measures to accomplish it. In either case we must not allow the present extreme industrial depression to obscure our view. We have passed through several depressions since the Civil War, and we have already turned the corner of this one.

The importance of our foreign trade requires but little defense. I may say, in passing, that our whole standard of living greatly depends upon our imports, and that our exports are the great balance wheel for our production. Exports are vital to the stabilization of our industries, of price levels, of wages and of employment. While our exports do cover but a small per cent of our total production, on the other hand they do comprise a large percentage of the production of certain industries. For instance, we generally export 20 per cent of our wheat, 60 per cent of our cotton, 75 per cent of our copper, not to mention others. **Unless we find a market for the surplus production of our great industries, we shall continue to keep some twenty-five millions of our people in reduced buying power.** We might even drive them into poverty—during the many years that would be required to shift the whole basis of our internal production. Nor does a nation become rich by its exports alone—but by its trade.

While many of the causes of the present depression lie within our own borders, yet there may be no recovery from these hard times for many years to come if we neglect our economic relations abroad. Even if we lower our vision of civilization in this crisis solely to our own

selfish economic interest, we are yet mightily concerned in the recuperation of the entire world. **The hard times that knock at every cottage door to-day came from Europe. No tariffs, no embargoes, no navies, no armies can ever defend us from these invasions.**

**Our sole defense is the prosperity of our neighbors and our own commercial skill. The recovery of our foreign trade can march only in company with the welfare and prosperity of our customers.**

As to our manufactures containing a large element of labor cost, in which we do not enjoy special advantages, we must look out and take measures of our own. We can no doubt devise tariff measures that will protect our domestic market. But if we are to hold to our foreign markets in this vast group of our manufactures, and thus to keep our people employed, we have several things to attend to.

**Fundamentally, we must get our production costs down. That lies only along the road of increased efficiency in our whole industrial machine. It means a willingness of our working people to put forth every effort that is in them consistent with health, proper family life and good citizenship. The surest road to a continued high wage, and the surest safeguard against unemployment is to remove every restriction on effort. This must extend from our mines to the railways, to the factories, to the wharf and to the ship. It means smaller margins of profit.**

It means that ultimately we must have much lower transportation rates. It means we must have better organized marketing machinery abroad under Americans themselves. It means the establishment of adequate short-time credit machinery and much more care in foreign credit risks than our merchants have shown in the last twelve months. It means elimination of the great wastes in industry. For instance, in the Atlantic seaboard area alone, by the development of these great water powers and through economies by electrification generally, we could profitably save 30,000,000 tons of coal per annum if we had the courage to go at it. It means the Government must remove as quickly as possible those unnecessary domestic burdens upon commerce to which the Government is a party by the reorganization of our tax system, the settlement of the tariff question, the reduction in Government expenditure through the reorganization of the Federal Government, through reduction of armament and through reduction of Shipping Board losses and by the settlement by the Government of the outstanding claims of our railways.

It means we must cease trying to drive American ship owners off the sea with tax-paid shipping losses. We must carefully determine what particular trade routes

we will maintain in development of our commerce over a period of years, and let our merchants know them. It means the Government must provide such information to commerce and industry, from both at home and abroad, as will enlarge its judgment. It means we must extend scientific research into the problems of waste, the perfection of processes, the simplification of methods that are beyond the ability of one manufacturer acting alone, and we must co-operate with industry to perfect these things. I am confident we can hold our markets, our higher standards of living and of wage if we will all put our backs into it.

In summary, on the production and marketing side of our commerce, we can say that our food exports should remain on a greatly enlarged scale; that the demand for our raw materials should slowly increase toward pre-war amounts; that in respect to our manufactures we should be able to hold special fields of repetitive production and ingenuity; that we will need to make a fight to hold the markets for manufactured goods where we come more directly into competition with the European manufacturer, but that we can do it if we will work and apply our brains to it. On the financial side of our situation, I do not believe our world credit situation is at all so insurmountable or that it requires extraordinary solutions.

#### As to Paraguay

Steady growth in the use of automobiles in Paraguay, one of those interior countries of Latin America which so often is seldom considered by export managers as offering an outlet for sales, is shown in a report to the Bureau of Foreign and Domestic Commerce by Vice-Consul George E. Seltzer at Asuncion. The mayors of the five most important cities in Paraguay have given the number of cars in their localities as of Jan. 31, 1921. The reports are Asuncion, 384; Villarica, 12; Concepcion, 40; Pilar, 4, and Encarnacion, none. It was estimated that at least 95 per cent of these are of American make.

#### If You Sell in Britain

A man who has long been interested in the merchandising of cars in Great Britain recently wrote to AUTOMOTIVE INDUSTRIES:

If it was my duty to instruct the American exporter of cars for the British and Colonial markets I would draw up a specification of requirements on these lines—bearing in mind that a compromise would be necessary to combine the requirements for two markets—domestic and foreign—which must of necessity be dissimilar and varying.

Gross weight with two- or four-seater body not to exceed 1500 lb.

Starter optional, but provided for.

Magneto ignition optional, but available also as dual with standard accumulator and coil set; variable timing.

European type of carbureter. Auto-vac or gravity feed optional.

Engine a "four" or "six," preferably the latter, en-bloc cylinders—not exceeding 2¾ in. x 5 in., with loose head, overhead valves with all inclosed valve-gear, light pistons, gravity cooling with provision for a circulator or impeller (not a centrifugal pump) for Colonial use, simple pump-assisted lubrication with more efficient details, and able to displace a large volume of oil, if required, for hot colonies; also a three-bearing crankshaft.

Three-point suspension and one-piece construction of engine, clutch and gear box, with ready access to the clutch for independent removal—this would entail a

longer and half-open clutch pan and housing than with present unit construction.

A four-speed and reverse gear and 4½-to-1 axle gear (spiral-bevel) ratio, axle gear removable from the back of the casing. Axle gear ratio of present American popular cars is a trifle too long.

Pressed metal axle casing and torque tube, no reliance on springs for drive thrust or torque.

No internal or sub-frame to chassis frame.

Double rear hub, side-by-side interchangeable brakes. Better steering than is usual with cheaper American cars.

Better grade body work as regards doors' fit and the depth of squabbing and seating, and details at large, including lamps. These and other details should be copied from a standard British light car, but with more leg room than average of British and French light cars.

Alternative model with two-, three-seater body—very popular among doctors and travelers, but must be roomy and well ventilated without being draughty. Latter remark applies also to open touring body.

Better grade radiators of cellular or film type than is sent here on cheaper cars.

Suspension quarter-elliptical throughout.

Gross or retail price in Britain not to exceed £250, or \$1250, at normal rate of exchange.

Commencing April 9, the Polish Government permitted the importation of passenger cars, upon which the customs duty is 13,500 Polish marks per 100 kilos (220 lb.) of weight. This report was made to the Bureau of Foreign and Domestic Commerce by Trade Commissioner Van Norman at Warsaw. Motor trucks, which have not been excluded, now take a customs duty of 300 Polish marks per 100 kilos.

#### Market in Algeria

A correspondent of the London Times Trade Supplement has drawn attention to the good prospects for motor vehicles in Algeria. He gives the following figures in support of his statement:

Number of vehicles recorded as actually in use at the end of March last 10,553, of which 8764 were cars, 1317 trucks, 310 omnibuses and 162 motorcycles. At the end of 1919 the total was only 8000.

In normal times Tunis and Morocco constitute good markets for motor vehicles, though they do not reach the importance of the Algerian market. About 2000 motor vehicles are at present in operation in Tunis, of which 1760 are cars and 165 lorries. Generally speaking, strong and simple machines are preferred of 8 to 15 hp. with four to five seats. Prices should be moderate.

It has to be pointed out that whilst French cars enter Tunis free of duty, foreign makes are heavily taxed. Consequently most of the cars in use are French. Next come American, Italian and British.

French Morocco is a market for 6000-7000 lb. trucks, which, however, must have large fuel tanks, and be sent out well supplied with spare parts; their mechanism must be simple and easily accessible, as, in most cases owners must carry out their own repairs, and the radiator should have a large cooling surface on account of the heat in the summer time. Particular attention should be paid to strengthening all parts likely to be affected by indifferent road surface.

One hundred fifty-four thousand seven hundred automobiles enter and leave New York every day.

Four hundred twenty thousand passengers arrive in New York by automobile daily.

# Remarkable Hangar Built for the Navy's Two Dirigibles

This building, with doors 170 by 264 ft. has some amazing features and is expected to serve as a model for docks for this sort of aerial conveyance. The measurements are: Length, 803 ft.; width, 264 ft.; height, 190 ft.

**T**HE U. S. Navy Airship Hangar at Lakehurst, N. J.—America's first great terminal for the giant airships which may be a common sight in this country within the next few years—is practically completed. It is the largest structure of its kind on earth, being 803 ft. long, 264 ft. wide and 190 ft. high. Set down in a city it would occupy three blocks. The doors at each end are more than 170 ft. high and are 264 ft. wide. A sixteen-story skyscraper could be pushed into the shed through the space disclosed by the doors when they are opened.

Rising from the Jersey flats, it presents an amazing spectacle to one on the ground. Observation platforms on the roof command a view of the Atlantic, 7 miles distant. In another direction, equally as far away, the fashionable summer resort of Lakewood can be seen clearly; while in the near vicinity the last of the 1400 acre reservation is being cleared to provide workshops, shelter and transport facilities for the 800 enlisted men and 500 civilian employees who will be required to man the hangar and care for the two great airships which it will shelter.

The airships are the Z.R.-1 and Z.R.-2, the former being built at League Island Navy Yard, Philadelphia, and the Z.R.-2, now undergoing trials in England. The hangar will be completed before the scheduled trans-Atlantic flight of the Z.R.-2 in August. The airships are each 700 ft. long and 85 ft. in diameter. They are as large as the great ocean liners. Capt. W. A. Moffett, Chief of Naval Aviation, an ardent believer in the future of aerial transport, is of the opinion that commercial aviation will receive considerable impetus from the operation of the Navy dirigibles and their terminal. Accordingly, all preparations at the Lakehurst hangar are with a view toward establishing facilities and conducting experiments which will aid commercial transport, and at the same time keep the public informed concerning the progress in the development of lighter-than-air craft.

In addition to the great hangar, the Navy plans to erect a mooring mast to which the big airships may be tied outside of other shelter. The mast will be so constructed that the giant ships will be moored bow on to the mast, and will swing in the direction of the wind, thus avoiding the dangerous forces exerted by high winds. The Navy contemplates also the erection of other mooring masts throughout the country, such as St. Louis, Kansas City, Chicago, Denver, San Francisco, Seattle, New Orleans, Atlanta, Columbus, Ohio, and San Diego, Cal. These will be based on results of experiments with the Lakehurst mast.

To-day the hangar is so nearly completed that Captain Moffett has assigned Comm. R. D. Weyerbacher, of the Bureau of Construction and Repair, and lighter-than-air expert for the Navy, to supervise preparations for receiving the Z.R.-2.

The doors of the hangar constitute the chief engineering

problem. Each leaf is made up of 800 tons of steel and corrugated asbestos. There are two leaves on each end, opened by sliding parallel with the front of the shed. Only they do not slide. Instead, they are supported on concrete trucks, which in turn rest on wheels the size of those on a freight car. Similar trucks set out from the doors and parallel to them support huge steel girders braced against the top steel framework on the doors, and acting as braces against heavy winds which sweep through the great shed with the ferocity of a gale. High winds would blow the doors apart if they were not properly braced, engineers assert.

Like the doors, the entire siding of the shed is corrugated asbestos, arranged in strips alternating between gray and two shades of brown, so camouflaging the shed as to break up its outlines and making it impossible for a hostile observer to identify it from the air.

Besides the railroad running lengthwise through the hangar, there are three trolley slots which are known as docking rails. The dirigible about to enter the hangar will be fastened by cable to these rails, which extend on a 1500-ft. runway at either end. Anchored to the rails, it will be a simple matter to guide the leviathans of the air into their berths.

Under the roof, among the network of steel rafters, five monorail cranes support movable platforms which enable the workmen to repair the airship after it is docked. The rafters are so far from the floor that a human voice cannot be heard. Workmen become mere specks as they move along the "cat-walks" which criss-cross the arches at dizzy heights. More than 16,000,000 lb. of steel have been used in the framework.

Supporting this are series of nine trusses forming arches. They are the largest of their kind, and are arranged in pairs. These iron girders are 172 ft. long.

The entire hangar is as fireproof as possible. The concrete floor is covered with asphalt to prevent falling tools striking sparks and exploding the gas, and, incidentally, to maintain warmth. The heating is entirely beneath the floor, distributed through three tunnels beneath the floor level. Wiring, wherever possible, is on the outside of the shed. The powerplant is located some distance away, as is the gas plant, which will have a daily capacity for manufacturing 75,000 cu. ft. of hydrogen gas, later to be increased to 100,000 cu. ft. capacity.

Searchlights on two diagonal corners of the hangar will guide the dirigibles at night. On the other two corners are flood lights which will illuminate the field to the extent of 20 acres. Sunken lights arranged like crosses have been installed at the end of each runway, also to facilitate landings at night.

A 25-hp. electric motor is used to open each leaf of the doors. It performs the work of some 1500 men who would otherwise be employed at great loss of time in dragging the doors away from the entrance.

## Power Required for Car Operation

*Editor, AUTOMOTIVE INDUSTRIES:*

This talk on operation on closed or nearly closed throttle is very much misrepresented. Based on operating a car in the city of New York there is some basis of truth, but for average conditions the idea that a car is operated on nearly closed throttle a majority of the time is truly rot. Under ordinary conditions the average car will do at a maximum about 45 miles per hour. This, under good conditions of level road and in the average shape that the usual owner keeps his car.

Now on usual road work I find in long distance running the average is around 25 to 30 m.p.h. or about two-thirds of the maximum.

In shorter runs quick acceleration and hill work take momentarily full throttle which brings up the average of power required.

While it is not my contention that a motor is run anything like constantly on a wide open throttle, the assumption that it is being run on the average from 75 to 90 per cent on nearly closed throttle is a pure fake.

I am not guessing at the above but base what I have said on my own actions combined with what I have noted on the road for many years.

GEO. M. BROWN.

The terms part throttle and part load are sometimes used interchangeably, but are by no means the same. When, for example, we speak of one-quarter throttle, we sometimes mean that the throttle valve has turned through one-quarter of its maximum angular motion, sometimes that the throttle lever on the steering wheel has moved one-quarter of its maximum motion on the quadrant, sometimes that the area by the butterfly valve is one-quarter of the area when the valve is wide open, or sometimes that the power developed is one-quarter of the maximum developed at the same speed when the throttle is wide open. As a matter of fact the power depends, other things being equal, upon the area by the throttle valve and the speed of the engine. For example, when the throttle is one-quarter open the engine may, at low speed develop 90 per cent or more of the power it is capable of developing at that speed, whereas at high engine speed and the same opening it may develop 25 per cent, more or less, of the power it is capable of developing at that higher speed. For these reasons it is necessary to be quite specific when we discuss part throttle operation.

If, however, our correspondent means that cars are not operated at least 75 per cent of the time at less than one-quarter load we are much inclined to disagree, for there is ample experimental evidence to the contrary. For example, a certain American car weighing about 4800 lb. and equipped with an engine of 295 cu. in. displacement, geared 4.5 to 1, requires\* the following b.h.p. to propel it on the level: 2 b.h.p. at 10 m.p.h., 5 at 20 m.p.h., 8 at 30 and 15 at 40. At the equivalent engine speeds the engine develops at wide open throttle the fol-

lowing b.h.p. 15, 32, 48, and 62 respectively. Consequently the per cent of full load at which the engine runs is as follows: 13 per cent at 10 m.p.h., 16 at 20, 17 at 30, and 24 at 40. It will thus be seen that at speeds under 40 m.p.h. the power required to propel this car at constant speed on a level road is always less than one-quarter of that the engine is capable of developing at the corresponding speed. Similar conditions will be found to apply in case of other cars.—EDITOR.

## Radial Air-Cooled vs. Other Types of Aircraft Engines

*Editor, AUTOMOTIVE INDUSTRIES:*

I note that Mr. Heron takes exception to my statement that "air-cooled engines were made in the radial form for cooling reasons rather than aircraft requirements." I do not believe his objection is really justifiable in the light of practical experience to date. In his letter, Mr. Heron refers to the British RAF-4A air-cooled Vee-engine as an example of what can be done in constructing air-cooled engines in other than the radial or rotary form. According to the best information in my possession the engine weighed 4.17 lb. per b.h.p. hour, had a fuel consumption of 0.68 lb. per b.h.p. hour, and an oil consumption of 0.067 lb. per b.h.p. hour. While these figures can undoubtedly be and probably have been improved on in other engines of this type, yet, the horsepower, weight, ratio and economy figures given, as compared with water-cooled engines, leave a great deal to be desired.

I wish to go on record as being a firm believer in the future of the air-cooled aircraft engine for certain purposes, and it is my conviction that the radial type offers the best field for development. I see nothing in the Vee type of air-cooled engine to commend itself except a reduction of resistance which in itself is open to question. The air-cooled radial engine has advantages in ease of cooling, ease of mounting, accessibility, compactness and possibilities in weight reduction, which to my mind would more than offset any slight increase in resistance as compared with the Vee-type of air-cooled engine.

Summing up, I think now, as always, that air-cooled aircraft engines will be used extensively in the future, and that of the three types, radial, rotary and Vee, so far constructed, the former has overwhelming advantages and deserves the greatest encouragement in development.

J. G. VINCENT,  
Vice-President of Engineering,  
Packard Motor Car Co.

**T**WO members of the Weights and Measures Division of the Bureau of Standards have recently visited several important gear manufacturers to obtain first-hand information as to the manufacturers' requirements in testing and measuring gears, gear cutters and hobs. Sufficient information was obtained to start the design of a machine for measuring the important elements of gears and gear-cutting tools.

# The Significance of the British Coal Strike Settlement

The provisions of the British coal strike settlement show practically nothing that could not have been agreed upon before the strike. Demand for larger voice in management likely to follow. No one is satisfied; a temporary compromise is apparently all that has been achieved.

By Harry Tipper

**T**HE final ending of the coal strike in Great Britain and the terms which have been agreed upon make it valuable to examine the character of this strike and the advantage secured by the workers, if any, to offset the amount of money lost and the net future revenue foregone in order to jockey for political advantage. Before the strike had been called, the government agreed to carry its subsidy for a sufficient length of time to enable the industry to swing over without undue hardship to the workers. The owners agreed to the profit-sharing principle, although the details were not worked out. The miners have secured in the adjustment of the strike practically nothing more than this allowance, except that the methods of profit-sharing have been worked out more completely in detail and provision is made for the supervision of the accounting in such a way that the workers' interest will be conserved.

The great principle of a national pool about which the miners made so definite statements is not included in the terms of settlement, the settlement being left to the various districts in accordance with their local conditions of settlement. This means that the local inequalities in wage will continue, and the local inequalities in profit on the profit-sharing basis will probably accentuate the individual character of the mining problem.

When due consideration is given to the desire on both sides to use the present situation for the pressure of advantage, the futility of uniform national machinery for the settlement of individual questions is very clearly shown.

The strike lasted about three months. How much it has cost Great Britain cannot be computed, because it will be many years before the total cost can be estimated. In the actual stoppage of industry the cost will run into the hundreds of millions of pounds.

The final settlement has secured no advantage for either side not suggested in the preliminary conferences before the strike actually occurred.

The only feature in the settlement worth considering at all is the extensive character of the profit-sharing agreement, affecting as it does all the workers in one of the basic industries. No experiment in profit-sharing of this magnitude has been attempted and there are no indications of its success in changing the situation.

Separate establishments do not make the same amount of money as profit, and this profit-sharing system adopted at the conclusion of the coal strike in Great Britain will lead to inequalities in the final rewards of the workers, due to the usual inequalities in the profits secured.

The miners have been very insistent upon a national wage and a uniformity of that wage. The present settlement does not lead in the direction of that uniformity, so that it does not lead in the direction in which this union organization has been moving for some time.

The miners have not shown disposition to accept any reductions in wages nor any reductions in their rewards, irrespective of the economic position of the industry and the effect of their demands upon the profits. There is nothing in the past history of the actions of the miners' unions that would indicate their willingness to base their reward upon the economic position or the profits to be secured in the industry. The present settlement indicates that a portion of their reward is to come from their share in profits. Whether they will expect to govern the prices in order that profits may be shown or whether they will accept the ordinary losses that occur from time to time in such a business is a matter for the future. Profit-sharing schemes have failed before now because the workers have not been willing to accept their share of the losses, and the disposition of the coal miners in their union action has not indicated any willingness on their part to accept such a situation.

A further question is likely to arise in connection with this powerful union and that is the question of their voice in the management of the mine properties. In some of their earlier demands they included the demand for a voice in the management, and this demand has not been less insistent than the other demands they have made. The present settlement does not carry any statements as to the management except those relating to the joint inspection of books, etc.

It would not be surprising if the present settlement led to a further demand for a larger voice in the management of the affairs of the mine properties, particularly as the profits will depend considerably upon the increased efficiency of mine operation.

Meantime there has been an increase in the standard wage and government provision for relief during the period of change. This last amounts to a government subsidy for the mine workers for a limited period.

The national pool and the national wage were political objects of the labor leader necessary to the continued growth of labor union power among its own members. Without nationalization of industry, labor unionism carried to the extent to which it has been in Great Britain has no object and cannot continue its development. It is based upon a program of uniformity, standardization and, therefore, of national agreement, and, finally, of nationalization.

Profit-sharing as secured in this settlement will not further the object of the labor union leader in this field unless such profit-sharing leads to a larger control of the management of the properties themselves. It emphasizes the difference where the object of the leaders has been to develop a common uniformity.

The uniform wage is a necessary part of the program for the continued development of labor union power and the control of production must be included in the objects, if the workers' organizations in Great Britain are to continue their growth along present lines.

These articles have pointed out many times the political aspect of the labor union movement in Great Britain, and the impossibility of securing any permanent settlement of industrial questions by means of these union developments.

It is significant that some of the leaders of the miners have stated that this is the last chance of peace in the coal trade under private ownership. This very statement would indicate that it is not a permanent settlement in the minds of the union leaders. They have accepted it under the conditions and with a faint hope that it may work out.

There is no evidence that the leaders are in full accord with the settlement or that they have abandoned their ideas on nationalization of mines and the development of a national wage system.

No part of their political program has been dropped in providing this settlement, although a good deal of it has been deferred until this particular compromise is given an opportunity to work out.

The very fact that the strike was allowed to go for three months and then settled on the basis previously suggested indicates that the settlement was made not because the objects of the strike were attained, but because the leaders felt that it was necessary to abandon the strike and to compromise upon any reasonable basis for the time being. The present settlement, therefore, does not satisfy the political desires of the labor party, nor the union objects of the miners. Its hope of success, rather, lies in its provision of opportunity for the individual worker to secure a reward based upon the value of the business and the individual advantage arising from the inequalities still existing in the settlement. This settlement, in fact, is a test of the strength of union organization among coal miners in many ways. If the union program is supported by a majority of the mine workers, this settlement would represent nothing more than a temporary compromise, accepted because it was necessary, but without agreement.

If the miner's interest in his own welfare and the maintenance of his local operations becomes of more visible importance to him under this settlement than the objects of the union, the power of the union to continue

its further program will be lessened to that degree and the present settlement may become the basis of a future agreement.

None of the other important parties to the settlement are entirely in accord with its terms. The liberal middle-class opinion, as represented by the Manchester "Guardian," is distinctly doubtful of the outcome, and the owners have made the settlement without the feeling that the plan itself is one with which they can fully agree.

The main points in the agreement are given so that the terms of the settlement may be understood, and are as follows:

National and District Wages Boards to be established, with equal representation of both sides and independent chairmen.

District wages to be in the form of a percentage upon the district basis rates, periodically adjusted, and determined by the proceeds of the industry in each district, ascertained after joint audit.

Wages above the standard to amount to a sum equal to 83 per cent of the proceeds, after allowance for standard wages, for other costs of production and for 17 per cent of the aggregate standard wages to be devoted to standard profits.

A subsistence wage for low-paid day workers to be decided by the District Wages Board or, failing agreement, by the independent chairman.

Standard wage to be the basis rates existing in each district on March 31 last, plus district percentages payable in July, 1914, or equivalents necessitated by subsequent adjustments.

The minimum rate will be the standard wage plus 20 per cent.

Items of costs are to be decided by the National Board or, failing agreement by July 31, by the independent chairman.

Wages up to August 31 to be based on the results of July, and for September to be based on the results of July.

During the temporary period of three months the costs of production will be based on the average of the first quarter of the year. The reductions during this period are not to exceed 2s. per shift in July, 2s. 6d. in August, and 3s. in September, providing that the balance of the government grant is sufficient.

The agreement is to last until September, 1922, and afterwards only to be terminated by three months' notice on either side.

There is to be no victimization, and men engaged temporarily during the stoppage are to give way to men working in their places before the stoppage.

The coal fields are to be divided into thirteen districts for the purposes of the agreement.

## Fuel Alcohol from Rice Straw

IN a paper recently read before the Indian and Colonial Sections of the Royal Society of Arts, Sir Charles H. Bedford referred to the production of industrial alcohol from rice straw. The suggestion to use rice straw came from Arthur Rogers, C.B.C., shortly after the termination of the war. Sir Charles decided on Burmah as a suitable sphere for operations and was able to secure the support of the Burmah Oil Company for carrying out experiments on a manufacturing scale. A distillery and laboratory have been erected at the company's refineries at Rangoon

and experimental work has been carried on there, as well as in England. The work is still in progress, but Sir Charles thinks it will shortly have been carried far enough for demonstration purposes, and he, and other technical and commercial experts, are satisfied with the results obtained. Other materials than rice straw will also be used to keep the plant in operation at all seasons of the year and this feature, combined with the utilization of certain by-products, is expected to materially reduce the cost of production.

## More About Commercial Bribery

RECENTLY we called attention in these pages to House Bill No. 5632, pending in Congress, which provides a strict penalty for the bribing of employees to induce them to recommend certain kinds of material as the proper purchase. It is the habit of manufacturers to-day to assert that this practice has been stamped out. Despite this belief on the part of many employers, the practice persists. The paint, varnish and glue industries have been seeking to rid themselves of this practice recently. The following paragraph is taken from a complaint filed with the Federal Trade Commission against a glue manufacturer:

That respondent in the course of its business, gives and has given to superintendents and other employees of proprietors of cabinet manufacturing establishments, and other establishments, without the knowledge and consent of the employers of such superintendents and other employees, cash commissions or gratuities, usually amounting to five cents per pound for all glue sold to said establishment by respondent, to induce such superintendents and employees to favor and recommend, and influence their employers to purchase, the products of

respondent, and to refrain from purchasing the products of its competitors, and without other consideration therefor; that the total sales of glue made by respondent exceeds \$500,000 annually; that such cash commissions and gratuities so given by respondent to the superintendent of the cabinet factory and to other employees of one of its customers, to-wit: the Talking Machine Company, during the two year period ending Jan. 1, 1921, aggregated approximately \$34,000, which resulted from the payment of a cash commission of five cents per pound on all glue sold by respondent, to such customer, for which glue respondent received thirty-five cents per pound; that respondent adds to its annual cost of doing business a sum equal to that paid out for cash commissions and gratuities as aforesaid, and is compelled to, and does add to the selling price of commodities sold by it, an amount sufficient to cover the amount so paid out for cash commissions and gratuities, which is in addition to the fair market value of such commodities.

This complaint goes on to state, in legal wording, that under such conditions it is quite impossible to have free and fair trade conditions. The company to whose employees this bribe money was paid is often referred to as one of the best-organized manufacturing companies in the country. Now that this bribery is discovered, the employer is helpless and cannot punish either the giver or taker of the bribe beyond his ability to discontinue his purchases from one and the discharge of the other.

Apparently there is a place for a law that would punish persons who betray their positions of commercial trust.

## What's the Difference?

SOME storage batteries supplied regularly with certain cars have a useful life of three or more years. Others supplied in similar cars of about the same grade have a life of one year or less. What's the difference between the two in first cost to the manufacturer, in replacement cost to the user, in construction, in bulk, in weight? These are pertinent questions in which a great many people are interested.

The number of factors which govern the life of a storage battery is admittedly great. Some of these are beyond the control of the battery manufacturer and the car builder, hence alibis are not difficult to find, and "passing the buck" becomes a favorite pastime when an effort is made to place the responsibility for the failure of a battery which must be replaced before it has served as long a life as can reasonably be expected. Almost invariably the car owner is the goat, for it is he who pays for the new battery, frequently after a period of difficulty in starting or ignition trouble, which sometimes occurs when a replacement battery is difficult to obtain.

Since, in nearly all American cars, the ignition, starting and lighting systems are largely or wholly dependent upon the battery, it seems evident that the car manufacturer should make certain that the battery equipment is at least on a par with the rest of the car in quality, instead of the weakest link, as it now appears to be in many cases. It is often said that some battery manufacturers sell to car makers batteries which not only are far too light and small for the service they will be called upon to perform, but sell these batteries at, or substantially at, cost,

figuring to make their profit in retail replacement sales at prices three or four times as great as the price to the car manufacturer. This would not be quite so bad if the expense ended with the first replacement, but the second battery is usually as inadequate as the first, since the user is not in a position to judge as to the basic reason for the failure, and, even if informed concerning the true facts, is unable to correct the fault for lack of space for a larger and more durable battery.

Whether this is a true picture of the average or quite general case, we do not know. We do know that a large percentage of batteries fitted are of inadequate size, and that they are a source of serious annoyance and expense which might be mitigated if the car manufacturer would spend a few extra dollars in providing a properly proportioned battery at the start. In so doing we believe he would serve his own best interests by avoiding service troubles. It is well to remember that a few extra dollars spent by the manufacturer will often save the user many times that amount. Ten dollars more spent in the original battery equipment may, for example, provide a battery that will last three years, whereas with the cheaper equipment two replacement batteries, perhaps costing the user \$40 each, in addition to the original, may otherwise be required to cover the same period of operation.

The day has passed when it is considered good business to build cheaply without regard to serviceability. The reputation which comes from failure of the finished product to perform with satisfaction over a reasonable period of time is not an enviable one.

We feel that there is need for more education, or at least more general appreciation of the facts, in regard to battery equipment and shall, as in all subjects of similar import, be glad to carry in our Forum columns an expression of the views of those interested in this important subject.

## Fuel Prices and Fuel Development

ONE of the hopeful signs as regards the immediate future of the automotive industry is the decrease in the price of fuel. Where a year ago as much as 34 cents per gallon was charged for gasoline at retail, it can now be bought for 26 cents, a decrease of 23.5 per cent. This tends to equalize matters in those branches of the industry where there is competition with other means of transport and traction, though, of course, the decline has been not at all commensurate with the drop in the cost of horse feed.

The cost of production of motor fuel depends largely on the cost of labor, and with the present situation in the labor market a gradual reduction in fuel prices is naturally to be expected. Another factor of importance undoubtedly is the general economic situation. Although the number of automobiles, trucks and tractors in service is probably greater than ever before, it is quite likely that the passenger cars, which, after all, consume the bulk of the motor fuel, are in many cases not being used as intensively as formerly and that, as a result, stocks of gasoline are accumulating.

A decrease in fuel prices will, of course, encourage increased use of cars.

The present decline in the price of gasoline will, no doubt, tend to check the development of substitute fuels. This development in this country has been entirely of a sporadic character. Interest in it declined some eight years ago, when the introduction of the cracking process resulted in a material decline in fuel prices and rose again when war activities led to an unprecedented demand for petroleum fuel, followed by a rapid rise in prices. In spite of the cost estimates sometimes furnished by optimistic inventors, it is fairly obvious that no fuel made from vegetable material specially grown for the purpose, or from mineral materials by involved processes, can compete with petroleum distillates so long as petroleum can be pumped from the ground in sufficient quantities. Therefore, while reports of the invention of new motor fuels occur in the newspapers at short intervals, they create hardly a ripple of public interest.

It is to be hoped that the decrease in fuel prices will not be the signal for cessation of effort to improve the economy of automotive engines, for the need for such improvement is just as real as ever. Prices of other commodities are also falling. The decrease in the price of gasoline may indicate only a temporary adjustment in keeping with the times, rather than a permanent reflection of supply and demand factors. Efforts to decrease waste are always commendable, and there is no lack of evidence that the car of to-day is wasteful of fuel. The world-wide effort to gain control of petroleum reserves is in itself a sufficient indication of the importance attached to providing a supply of this fuel for the future. Let no one be deluded into thinking that it is less necessary than formerly to conserve our domestic supply.

## License by Weight

AN interesting experiment in the licensing of automotive vehicles is under way in Kansas, where the fee is based on weight of the motor car or on the useful load to be carried by the truck. Previously the license fee has been based upon the horsepower of the car and any one of several rather unsatisfactory bases for trucks.

When the Kansas license officials undertook to carry out the law, they found some unexpected (to them) obstacles. First was an inability to obtain a list of weights of the various cars. The Secretary of State wrote to the factories for the shipping weight, as he interpreted the law to mean the gross weight of the motor car as it stood in the salesroom. The weight adopted does not include gasoline, oil or water. In instances where the manufacturer did not supply a statement of the weight, the licensing officials caused an applicant for a license for a particular car to take the car to a scale.

There has always been objections to the license fee based on the horsepower of the motor car, the objectors asserting that this was in the nature of a luxury tax. A comparison of the fees involved in the two methods would shed some light on the subject of fairness of the two methods.

# July Business Surpasses Early June

## Barometer of Trade Rises Along Coast

**California Shows Steady Gain  
with Every Prospect for  
Improvement**

SAN FRANCISCO, CAL., July 20.—The barometer of trade in all branches of the automotive industry is rising steadily in California. The southern part of the State is busier in these lines than the north, but the north shows steady gain, with every prospect of improvement. It is still a buyers' market, and the buyers are more critical than ever, but more people are buying cars than have been buying them for the past eighteen months. In other words, the market for the right car, at the right price, never was better in the territory for which San Francisco is the center of distribution for automotive vehicles and equipment.

This is a brief summary of conditions as voiced to the correspondent of AUTOMOTIVE INDUSTRIES by a large number of dealers in San Francisco and in Oakland and Berkeley, on the eastern shore of San Francisco Bay. General reductions in the prices of virtually all cars is held to be responsible for the improved trading, but greater freedom of money and better prospects also are indicated by the increased demand for used cars, on which prices are virtually the same as they have been for the past six or eight months.

In no other industry on the Pacific Coast is this tendency to get back to a wholesome pre-war basis in the matter of movement of goods, merchandising prices and desire to buy, more marked than in the automotive industry. The demand is for the best possible car at the right price, and the reduction in prices by the factories, without reduction in quality of car delivered, has been a factor in bringing about the improved condition.

The passing of the so-called "price flurry" seems to have stabilized the business of buying, selling and distributing automobiles to greater degree than any one factor since the dealers came to realize that the time of hustle-for-orders, rather than sit-down-and-wait-for-buyers, had arrived.

### Denver

DENVER, July 20—Automobile sales seem to average slightly better than for the first half of June with less restlessness.

(Continued on page 146)

## JULY SALES BRISK IN ALL DISTRICTS

NEW YORK, July 20—Dispatches to AUTOMOTIVE INDUSTRIES from its correspondents in the principal distribution centers show that the volume of automobile sales at retail for the first half of July has been extraordinarily good as compared with the same period in June. While it is probable there will be the perennial mid-summer decline in the sales curve, it has been deferred later than usual in many cities. July business thus far has been better than either dealers or manufacturers dared hope it would be. Up to this time there has been practically no curtailment of factory operations and in some instances schedules have been increased.

Sales for the first half of July were better than the first fortnight of June in these cities: Detroit, Des Moines, Denver, Salt Lake City, Dallas, Cleveland, Columbus and Indianapolis.

July sales have held their own with June in Chicago, Milwaukee and Philadelphia.

July has shown a falling off as compared with June in New York, Minneapolis, New Orleans and Atlanta.

The Metropolitan slump is due to the universal exodus to summer resorts by persons able to buy cars. In the Northwest interest is centered on the harvest. In the South the continued low price of cotton has exercised a depressing influence.

San Francisco reports increasing business while Toledo and Louisville are holding their own.

## Chicago Keeping Pace with Business of June

CHICAGO, July 20—Business for the month in Chicago is keeping up the pace established in June, and June business, under the influence of reduced prices, was far in excess of recent averages. Buick, Studebaker and Dodge are leading the medium priced car field, but practically all dealers declare sales conditions satisfactory.

Country sales are still slow, but showing improvement. There are an increased number of inquiries along the Row, a fact which convinces dealers that there will be a continued steady demand, with a likelihood of a spurt in the agricultural districts following harvesting.

## Salt Lake Territory Shows Improvement

**Retail Business Holds Up Well  
During First Two Weeks of  
July**

SALT LAKE CITY, July 20—Retail automobile business in the larger cities and towns in the Intermountain territory has shown a steady improvement during the first half of July. Salt Lake, Ogden and Provo, Utah, and Boise, Idaho, dealers, are showing a better working spirit than is manifested by the less highly organized dealers in the smaller towns and communities. Wholesale business is at a standstill and dealers are largely dependent on their retail efforts to equalize their sales.

The retail business is holding up well under the general business slump largely because sales managers and salesmen are overlooking no opportunities. Salt Lake distributors particularly are diligent in pursuing prospects. Tourist trade during the last six weeks has aided the industry materially and the repair business is by this reason considerably better than during the spring.

Price reductions coming on the 1st of July have also helped to stimulate sales. Tires, accessories and batteries are registering a lively trade.

P. F. Drury, assistant general manager of the National Automobile Dealers Association, is visiting in Salt Lake. At an address before the Intermountain Automotive Trades Association he stressed co-operative methods and association work. From here he will go to Boise, then to Portland, Tacoma, Seattle, and he will be in Spokane the 27th, 28th and 29th of this month to attend the annual meeting of the Washington Automobile Chamber of Commerce.

### Philadelphia

PHILADELPHIA, July 20—Retail automobile sales for July thus far compare very favorably with June sales. Prospects are for considerably improved trade. Sales of new cars are 45 per cent of the entire June sales. This is considered owing largely to reduction of prices which is now considered over.

Another good sign is the falling off in sales of used cars which were good earlier in the season but now are quite flat. In new cars high priced automobiles are beginning to sell as well if not better than the less expensive types.

Truck sales continue dull. The trucking business is not heavy.

# Sales Increase Holds Up in Nation

## Notable Sales Made in New York District

### July Not Subnormal in Metropolitan Buying—Vacations Cause Usual Slowup

NEW YORK, July 20—Passenger car sales which ran high throughout June in the metropolitan territory have dropped considerably during July up to date and the majority of dealers expect the falling off for the month to be more or less comparative with that which prevailed in normal years before the war.

Oldsmobile, Scripps-Booth and one or two other cars which had price reductions late in June after the novelty of most of the competing reductions had worn off sold better during the first two weeks in July than in previous months. However, the normal run of cars including the strongest sellers have showed considerable dropping off in day by day sales.

The indications are that the July sales record will be considerably below June, but nothing subnormal as July goes in New York City, with a great many people in the automobile owning class out of town on vacations.

Some notable sales records were made during June. Dodge sold at retail within the limits of New York City more than 400 passenger cars and 100 trucks. It is said that this has not been equalled except in cases where distributors included sales in outlying territories in their New York reports.

Nothing has developed to indicate that there will be any severe curtailment of buying during July and August. Dealers generally expect business to be slow but in this respect they will just be going back to normal conditions prevailing before the rush for cars two years ago.

## Indianapolis

INDIANAPOLIS, July 20—It is expected that retail sales for the first half of July will beat sales for the same period of June by from 10 to 20 per cent. Dealers say that sales are good for the time being but they are pessimistic concerning future business. Those dealers handling cars on which reductions were made last month or during the last six weeks are reporting an exceptional business which will show a dollars and cents increase in spite of reductions. Dealers in the higher priced cars say business is showing better so far this month than it has during the year and these dealers are rather confident concerning business

during the remainder of the year. It is probable that Studebaker and Haynes cars are leading the field in their class, while the dealers in Dodge, Ford and Chevrolet all report increased sales during the month. One reason for the increased sales made, dealers say, is the fact that money is loosening up a little, though credits are yet very much restricted. Business in used cars also is showing a decided increase and dealers say that if the industrial situation continues to improve it is probable that further increases in used car sales will be recorded.

## Milwaukee

MILWAUKEE, July 20—The June record of retail sales for Milwaukee and vicinity will be maintained for the first half of July. Representative dealers see no indication of material slowing tendency but do not expect inflation during the remainder of the summer. The public apparently is not satisfied that prices have reached bottom. Rumors of impending supplementary reductions in Ford prices early in August have a disturbing influence on account of the expectancy that other cars must follow.

Expressions by eight big dealers give a general average of equality between sales for the first half of June and July. Distributors report wholesale business smaller, which is customary following the passing of midyear with country districts busy with crops.

## Detroit

DETROIT, July 20—Steadily increasing averages mark daily sales of Detroit dealers in standard automobiles. Volume for the first 14 days of July indicates an average increase for the month over June of 28 per cent. Largest percentage of increases were reported by Dodge, Overland, Buick, Oldsmobile, Studebaker and Hupp dealers though practically every one reports better business than in June.

Careful investigation of conditions by officials of the Detroit Automobile Dealers Association shows distributors and dealers optimistic and confident that the increased demand is not a flash in the pan but normal spring business delayed by unsettled price conditions and bad weather during April and May.

Price cuts naturally proved a stimulant to buying and nothing is in sight now to indicate a slump in demand, according to Guy O. Simons, president of the dealers association.

## 20 Per Cent Increase in Des Moines Field

### July Sales Will Beat Those of June—See All-Summer Business

DES MOINES, July 20—Interviews with 10 leading Des Moines dealers show that stimulation of business has held up well during the first half of the month, in fact, improvement of approximately 20 per cent over June is noted by all dealers. This refers only to retail city sales as country business with the exception of Dodge, Overland and Ford is practically at a standstill. Final figures for June showed 10 per cent improvement over May.

Eight of 10 dealers interviewed forecast continuance of present business until late September or early October. The other two expect a let down by late August. Truck sales are at a minimum.

Second hand car business is brisk at readjustment prices. Money is somewhat easier in the city and collections are fair but there are no signs of improvement in credit conditions in the country. July sales in the city are practically on a par with July, 1920. The major part of the improvement over conditions of spring and early summer is attributed to the stimulation of price cuts.

## Minneapolis

MINNEAPOLIS, July 20—Business in automobiles has shown a slump in July as compared with June in the Northwest territory. Just now the farmer mind is centered on his harvest and a new spurt cannot be expected until this harvest is in. Crop conditions are generally favorable notwithstanding the long period of hot weather. With a good harvest better conditions are expected.

The Fourth seems usually to be a cut-off line in the motor business and at that time the public loses interest in new cars, all having bought that have considered the matter seriously. A firm which did three times its business of June last year notices the slump strongly.

A large distributing firm with a crop service of its own, which reports a big drop in sales as compared with June last, believes crop news from the sun-burnt districts is mostly local and the crop as a whole promises well, if not a bumper, as expected. In North Dakota three-fourths of the State shows an exceptionally good outlook, in fact, better than last year.

## Leaf Spring Forms Group in M. A. M. A.

Second to Organize Into Separate  
Body—Score of Others to  
Follow

NEW YORK, July 18—The Leaf Spring Institute has dissolved as a separate organization and will continue its work as the leaf spring group of the Motor and Accessory Manufacturers Association. It is the second to be organized of some 28 groups of manufacturers with more or less like interests which will be formed within the M. A. M. A. H. R. McMahon, president of the Standard Steel Spring Co., has been elected chairman of the group, Mason Rumney of the Detroit Steel Products Co. vice-chairman, and E. R. Busby of the William & Harvey Rowland, Inc., secretary and treasurer.

Plans for the organization of the entire membership of the M. A. M. A. into groups will be carried out at once. The two groups already formed will be followed by groups in the following lines:

Asbestos products, axles, bearings, bumpers, carburetors, chains, clutches, engines, fans, forgings, foundries, gears, lamps, piston rings, radiators, shock absorbers, spark plugs, springs, startings-lightings-ignitions, steel producers, steel products, tires and tubes, tops, transmissions, warning signals, wheels, wind shields.

Among the subjects now before the association for standardization consideration and which will be referred to the respective groups following the division of the membership, are:

Design, purchasing specifications, construction, materials, cost systems, specifications, weights, dimensions, sales contract forms, packing, shipping, invoicing forms, guarantees, advertising, service methods. Upon a group taking favorable action on any subject of standardization, which will be by two-thirds of its members approving, the plan shall become effective by approval of the board of directors of the association.

A significant feature of the group plan is an arrangement whereby the chairmen of all groups constitute an advisory committee to the executive committee of the board of directors and an advisory board to General Manager M. L. Heminway. The president, first vice-president, secretary and general manager and general counsel of the association are ex-officio members of all groups.

### BATTERY COMPANIES MERGE

MARSHFIELD, WIS., July 18—The Stewart-Galvin Battery Co. and the Stewart Storage Battery Co. have been consolidated in a new corporation to be incorporated in Wisconsin, which has decided to locate its permanent works and headquarters in Marshfield, Wis. For the present the company will occupy the building of the Marshfield-Franklin Co. and employ 50 to 75 operatives.

## WANT NEW YORK SHOW AT GRAND CENTRAL

NEW YORK, July 20—The 1922 New York automobile show will be held, in all probability, in the Grand Central Palace instead of in Madison Square Garden as originally proposed. Negotiations to this end have been practically completed although a few details remain to be cleared up. This arrangement, which will be eminently satisfactory to every one concerned, is made possible by the fact that plans for converting the Palace into an office building have been delayed. The Garden still is available in case of emergency but its use would involve very heavy expense because of alterations which would be necessary in the building. The rental charged for the Palace will be much higher than in the past but the N. A. C. C. has decided that nothing must be permitted to interfere with the success of the show next year.

## \$6,000,000 in Contracts Let for Roads on Coast

SAN FRANCISCO, July 20—Contracts for construction of highways, let by the State of California between Jan. 1 and July 1, this year, number 35, with total value of \$6,000,000. The work is distributed all over the State, and bids on other sections are now being asked, with prospects that a total of half as much more will be let within the next ninety days. The State-wide extent of these road construction contracts may be gathered from the fact that the work is in the following counties:

Fresno, Tehama, Shasta, Santa Barbara, Kern, Humboldt, Butte, San Luis Obispo, Mendocino, Placer, Nevada, Sacramento, Amador, Solano, San Mateo, Tulare, Los Angeles, San Diego, Mono, Mariposa and Glenn.

The United States Bureau of Public Roads has signed up with the California State Highway Commission for the expenditure of the remaining money in the allotment of \$2,896,071.77 given to California under the 1921 allotment of Federal road moneys. The money will be spent on 24 highway projects in this State. This agreement puts all the money available for California under the 1921 allowance actually to work, under way, or agreed upon. The moneys available for the 1922 allotment will have been agreed upon or put to work before June 30, 1922.

### PATRIOT REORGANIZES

LINCOLN, NEB., July 18—The Patriot Motor Co., manufacturer of Patriot trucks, which has been operating under a receivership since last November, has been reorganized and will continue in the truck field. The assets recently were acquired by a new company.

## Coast Trade Is Good, Says Goodyear Man

Los Angeles Factories Increased  
Production 47 Per Cent  
Since March

AKRON, July 20—Business conditions are improving rapidly on the Pacific Coast with every indication of a quick return to normal, according to A. F. Osterloh, former sales manager of the Goodyear Co. of Akron and now vice-president and general manager of the Goodyear Co. in Los Angeles. Osterloh and other California Goodyear officials arrived in Akron to-day for a conference with President E. G. Wilmer, relative to production on the coast.

The Los Angeles Goodyear factories have increased production 47 per cent since March, now being on a basis of 3500 casings and 3700 tubes daily, according to Osterloh. This is the largest production in the history of the Western company which started production in June, 1920. With the demand for tires steadily increasing, further production increases are contemplated both in Akron and at the Pacific Coast factories. The Akron factories report this week's dealers' business was the heaviest in the company's entire history. Stocks are low and indications point to a tire shortage if the present rate of buying continues, unless manufacturers greatly increase production. It is stated by experts that there is now less than a 30-day supply of tires on hand in the United States. Experienced tire builders considered desirable for re-employment in the Akron factories are scarce. The Akron tire factories are endeavoring to build up their forces by putting on married men and home owners, and are trying to prevent an influx of transient floaters to Akron.

### Here for Conference

In the California party now in Akron are Osterloh, C. C. Slusser, factory manager at Los Angeles; Sales Manager J. R. Reilly, and Treasurer W. A. M. Vaughn. C. H. Carlisle, treasurer and general manager of the Goodyear Canadian factories, also is here to confer with Wilmer as to plans for increased production. Other Canadian officials here with Carlisle are R. P. D. Graham, vice-president of the Canadian Goodyear Co.; H. C. Lower, sales manager; H. G. Layne, assistant treasurer, and E. H. Koken, general superintendent.

### RECEIVERSHIP IS DENIED

KANSAS CITY, MO., July 20—Application for a receiver for the Beggs Motor Co. of Kansas City, manufacturing the Beggs car, was denied in Independence, Mo. The court, upon hearing, decided that on the showing made the company was not insolvent. Stockholders having a small amount of shares brought the suit.

## Packard Dealer Gets Durant Car On Coast

### Earle C. Anthony Will Handle New Make at Four Important Pacific Points

SAN FRANCISCO, July 20—First announcement regarding the marketing of the new Durant car in California is released by R. C. Durant of the Durant Motor Co., with the news that Earle C. Anthony, Inc., for 16 years Packard distributors in this State, will handle the Durant at the four most important distributing points in California—San Francisco, Oakland, Sacramento and Los Angeles. In all of these places the Anthony organization has branches.

At the same time, Mr. Anthony announced that George R. Bury, who, until July 1, 1921, had been general sales manager of the Packard Motor Car Co., had been appointed vice-president and assistant general manager of Earle C. Anthony, Inc., and will devote all his efforts to northern California territory. Bury had been more than fourteen years with the Packard company. The arrangement between the Durant company and the Anthony firm marks an alliance between America's newest car and one of California's oldest and strongest automobile concerns. The founder and president of the distributing company is Earle C. Anthony, a pioneer in the motor car business in this State, having entered the business in Los Angeles in 1904. In 1905 he became Packard distributor for Southern California, acquiring the whole state for that line four years ago. More than eight years ago he entered the state distributing field, at that time with Chalmers, but this was replaced in 1915 by the Reo, which Anthony relinquished July 1 in order to devote the entire energies of his company to the Packard line and to preparations for the marketing of the new Durant upon its arrival. The Anthony organization conducts its own stores in San Francisco, Oakland, Sacramento, Fresno, San Jose, Bakersfield, Los Angeles and San Diego.

R. C. Durant heads the Durant Motor Co. of California, a subsidiary of the Eastern parent concern, and a \$3,000,000 factory in Oakland will be producing Durant cars by December of this year. Associated with R. C. Durant are C. M. Steves, A. L. Warmington, George R. Scott, H. T. McKnight and Charles H. Durham.

### RECEIVERS ARE OPTIMISTIC

COLUMBUS, July 20—Receivers W. C. Willard and George A. Archer of the Allen Motor Co. of Columbus announces that orders are coming in much better and that during July it is planned to turn out 200 cars, all on orders. The outlook for the future is now much brighter, according to the receivers. A total of 200 workmen are now employed at the Columbus and Bucyrus plants.

## TRAFFIC SO GREAT WILL WIDEN ROADS

HARRISBURG, PA., July 18—Preliminary studies of projects for increasing the width of main State highways entering the larger cities of Pennsylvania so that they may be ultimately extended to 100 or 120 feet, are under way by State Highway Department engineers. The rapid increase in motor traffic has made it imperative to create future building lines. Studies nearest Philadelphia have been in Delaware, Buck and Montgomery counties and in the Main Line district.

## Warehousemen Urging Service Parts Stations

LAKE OF BAYS, ONT., July 18—The National Furniture Warehousemen's Association, comprising more than 500 household goods and furniture storage-men, the majority of whom operate motor trucks, adopted a resolution today, at its convention here, addressed to the unit parts manufacturers of the country requesting them to establish service parts stations where distributors and agents could furnish not alone present supplies but parts long considered obsolete.

The resolution set forth that if such stations could be established where both old and current models of parts could be obtained, this would tend to stabilize prices, would prevent price advances, would assure immediate deliveries for customers and would give the maximum efficiency to which those patrons were entitled.

The Pacific Coast Furniture Warehousemen's Association and the California State Draymen's Association have adopted a similar resolution it was disclosed.

### REMY ELECTRIC TO REOPEN

ANDERSON, July 20—Remy Electric Co. plants which closed down July 8 will reopen next Monday, according to announcement. New business added to incomplete orders in sufficient quantity for operation on the same scale as has existed for several months is understood to have been added. Higher efficiency of labor is said to be one factor in the reduced force that has been operating the plant.

### RECEIVER FOR TIRE COMPANY

INDIANAPOLIS, IND., July 20—The petition for the appointment of a receiver for the Federal Rebuilt Tire Co. of this city was filed by H. R. Morgan & Co. recently, alleging that the company is in danger of insolvency. Jacob Morgan, a local attorney, was appointed receiver for the company by Judge Solon J. Carter and has started to work out the company's affairs.

## Million in Revenue for Standard Parts

### Receiver Reports Rush of Business—Profits Large in Last Two Months

CLEVELAND, July 20—The Standard Parts Co., a \$20,000,000 corporation making automobile parts and accessories, which has been in the hands of a receiver since last September, has been making money in the last two months.

John Younger, who is in charge of operations for Receiver Frank A. Scott, says that the company's showing is proof that the automobile industry is healthy and business is good. The Standard Parts in recent months has obtained considerable new business and has taken on some big contracts from concerns that are operating at capacity and are rushed with orders. The gross revenues have been running approximately \$1,000,000 a month lately.

Action taken by this corporation on July 1, in consideration of the recent reductions in prices of steel announced by the United States Steel Corporation and the Bethlehem Steel Corporation, is regarded significantly by the trade here.

Since July 1 the Standard Parts has been quoting low prices on springs, tubings, rims, and other products manufactured by the corporation.

For some time the corporation has been operating all of its plants, as follows: The Bock Bearing, Perfection Springs, Standard Welding, Eaton Axle, Canton Drop Forge, and Pontiac Spring Co. No statement was made at the local headquarters offices with respect to the size of the staffs working, but it was learned that it is near normal. In addition to the above plants, the corporation is operating spring service stations in New York, Boston and Cleveland.

The receivership has helped officers of the company greatly by giving the corporation stability in these times. It has the power of the United States court back of it and with this backing all orders are being promptly fulfilled.

A short time ago the common stockholders asked the court to continue the receivership for the time being.

The creditors of the company are to meet here August 10 to discuss what shall be done with respect to the receivership. They had advanced a plan for the formation of a new company to take over the assets from them and reports will be made on the progress of this at the meeting. Stockholders have not regarded this proposal with favor.

### H. C. S. TO MAKE CLOSED BODIES

INDIANAPOLIS, IND., July 20—The H. C. S. is planning to get into the manufacture of closed bodies some time in August. At the present time the company has completed its first limousine. The job has wire wheels and the body is of aluminum construction.

## Committees Study Contract Changes

### N. A. C. C. and Dealers Consider Amendments Covering Cancellations, Etc.

NEW YORK, July 18—The committees representing the National Automobile Chamber of Commerce and the National Automobile Dealers' Association in the promotion of closer relations between the manufacturers of motor cars and their distributors are giving close consideration to proposed amendments to the present form of contract. Three important changes have been proposed by the dealers. They cover cancellations of contracts, allotments of motor vehicles and depreciation in the value of motor vehicles and parts. These are the major points covered.

Directors of the N. A. C. C. were to have considered the subject at their meeting in Buffalo last week, but the draft of the proposed changes was not received from Harry Harper of Philadelphia, former president of the N. A. D. A., until just before the meeting opened, and it was decided to defer any discussion until there had been opportunity to study the subject. In the meantime they will be taken up by the committees in preparation for a joint meeting, which will be held in the near future at a date not yet determined.

The committees representing the two organizations are carrying on their discussions in the most friendly spirit and marked progress has been made in the deliberations. There is evident a strong spirit of mutual helpfulness with the realization that what helps the dealer helps the manufacturer and vice versa.

In addition to contractual relations, the dealers are expected to urge that changes in models and prices be announced in future at the time of the big shows instead of spreading them over the entire year.

The N. A. C. C. directors at their Buffalo meeting decided to take a monthly census of production and sales in the industry to be reported to Secretary of Commerce Hoover, as he has requested. Only the totals will be given and there will be no details concerning individual companies.

In connection with the \$5,000 which will be offered in prizes to the school children of the country for the best essays on accident prevention on the highways, it was decided to offer special prizes to the teachers who supply the best lessons on "safety first." The prizes will include cash and trips to Washington.

### REFUSES REFUND ON TAXES

RALEIGH, N. C., July 20—State Treasurer B. R. Lacy has formally declined to make any refund of automobile license taxes paid to the State by automobile manufacturers or their representatives in the State. J. S. Griffin, a Raleigh attorney, representing the Olds

Motor Works, the Kissel Motor Car Co., the Cole Motor Car Co. and the Marmon Motor Car Co., had made formal demand on the treasurer for a total refund of \$6,000, representing sums paid in by his clients in compliance with the State law. Invalidity of the revenue act, so declared by the United States Supreme Court, because of discrimination in favor of North Carolina corporations is the reason assigned for the demand. Treasurer Lacy, replying to the formal demand, says: "In reply will say that after consultation with the attorney general I am advised by him not to refund any of these license taxes."

## Airplane Inquiry Will Disclose Engine Ideas

WASHINGTON, July 20—Information of great value in designing airplane engines in the United States is promised by the Bureau of Standards in forthcoming final reports to be made in connection with a thorough investigation that has been completed as to the performance of two well-known makes of German airplanes. The investigation was made through co-operation between the Bureau and the Air Service at McCook field.

The two engines which have been investigated are known as the B. M. W., 185 hp., and the Maybach, 300 hp. Both machines are of the 6-cylinder type which has long been a favorite in Germany.

It may be of interest to note, the Bureau reports, that the performance of the B. M. W. engine at high altitude was excellent, its low fuel consumption being the outstanding feature of merit. The chief point of interest in connection with the Maybach was the design of the carburetor, which, however, cannot be considered as entirely satisfactory as, although it gave excellent economy of fuel, the efficiency of the engine at part load was rather poor.

### COURT HALTS USE OF NAME

NEWARK, N. J., July 20—Samuel Ehrlich of the Hudson Tire Co., Inc., of this city has just obtained an injunction in the United States District Court, Southern District of New York, against the Hudson Tire & Rubber Corporation, W. M. Doucette, H. B. Seymour and Ulrich Wiesendanger, restraining the corporation and its officers from using the name "Hudson" in connection with their business.

Ehrlich claimed that the defendants were fraudulently making use of the name "Hudson" in connection with their business, well knowing that Ehrlich had been doing business as Hudson Tire Co., Inc., in Jersey City and Newark for several years.

Ehrlich has been selling Hudson tires in Newark, all of the New England States and practically throughout the United States, and is now arranging to establish agencies for the sale of his tires in every State and section of the United States.

## Palmer Charged with Undue Favoritism

### Bosch Magneto Sale to Supposed Friend "Fixed," Complaint Says—Makes Denial

NEW YORK, July 18—Charges first made last year that A. Mitchell Palmer had shown undue favoritism to Martin E. Kern of Allentown, Pa., in the sale of the assets of the Bosch Magneto Co. which were sold by Palmer as Alien Property Custodian in 1918 for \$4,150,000 have at last been made openly. The company then was reorganized under American control as the American Bosch Magneto Corp. The allegations have been denied by Palmer as "part of a drive by Germans to influence Congressional action so that they may regain their properties sold when this country was at war with Germany."

It is asserted that Kern was "a close friend and business associate" of Palmer, that Kern valued the property at \$8,000,000 three weeks after he bought it, and that the auction of the assets was "fixed" so there would be no competitive bidding. It also is charged that:

The Bosch company's controlling interest in the Boonton Rubber Manufacturing Co., of which the Bosch company held more than one-half the stock, was held for \$1,000 to Kern.

The 130 patents held by the Bosch company were sold to Kern for \$1. The Reading Standard Co., manufacturers of motorcycles, of which the Bosch company held more than one-half the stock, was sold for \$1.

The St. Louis Car Co., in which the Bosch company invested \$100,000, was sold for \$1.

The good-will of the company and its various valuable trademarks were turned over to the purchaser gratis.

Palmer did not advertise the sale widely, and held it "in the woods" on the outskirts of Chicopee, Mass.

Palmer characterizes all the allegations as "nonsense." The whole question was threshed out before the Senate Judiciary Committee two years ago, he asserts, when his name was presented for confirmation as attorney general and the committee decided unanimously that the charges against him were unfounded.

### SOUTH CAROLINA USES LESS GAS

COLUMBIA, S. C., July 20—South Carolina used less gasoline and kerosene for the first six months of 1921 than for the first six months of 1920, according to figures compiled by H. W. McCreight, chief clerk of the Department of Agriculture. From January through June this year 28,161,768 gallons of gasoline and kerosene were shipped into South Carolina, as compared with 31,787,608 in the same period of 1920. These figures are available from the tax imposed on the two products and do not absolutely mean that more gasoline and kerosene were used in the first period than in the second. The figures for gasoline alone are: For the first half of 1920: 21,291,739; for the first half of 1921: 18,907,178.

## U. S. Considers Ford Offer for Big Plant

### Muscle Shoals Nitrate Property May Be Taken on 100 Year Lease

DETROIT, July 18.—Announcement made in AUTOMOTIVE INDUSTRIES three weeks ago that Henry Ford had inspected the huge Government nitrate plant at Muscle Shoals with a view to making an offer for it has taken concrete form and Congress now is considering an offer from him to lease the property for 100 years. He has submitted the following proposals through the Secretary of War and the Secretary of Commerce:

First—He will take a 100 years' lease upon the Wilson Dam and No. 3 Dam and electric installation when completed. This work is estimated to cost \$28,000,000. After a short preliminary period, Mr. Ford proposes to pay interest at the rate of 6 per cent on the sum of \$28,000,000 and to amortize not only this sum but of the entire cost of both dams over a period of 100 years.

Second—To purchase all nitrate plant and equipment, lands, steam plant, etc., for \$5,000,000.

Third—To convert and operate the large nitrate plant (No. 2) for the production of fertilizer compounds and as a stand-by for Government explosives in case of war, and to keep it up to date in both lines.

Fourth—To limit the profits of the fertilizer plant to 8 per cent; an independent board embodying representatives of the American Farm Bureau and the National Grange and the Farmers' Union to certify to this maximum.

The completion of these works makes the Tennessee navigable to Chattanooga and there are undertakings by Mr. Ford for maintaining the locks, etc. The power development will ultimately greatly exceed the requirements of the fertilizer plant, and Mr. Ford proposes to use it in his own business. In order to meet the annual payments proposed, a very large use of power must be made outside the fertilizer works.

### U. S. Ready to Lease

Secretary Weeks has several times expressed his willingness to recommend to Congress that appropriations necessary to complete the work at Muscle Shoals be made, provided some substantial business concern would agree to take over the project on such terms as would benefit the nation and the Government.

Ford has made no statement regarding the use he proposes to make of the surplus power, but it is understood he intends to operate on the banks of the river a southern unit of his automobile factory from which he will be able to serve a huge territory at lower costs. There also are reports that he intends to specialize in tractor development in the South. It also would be possible for him to sell power for manufacturing plants over a large area.

## CAR BUYERS EMPLOY MONEY-SAVING PLAN

NEW YORK, July 18—Passenger car dealers have had experience lately with a new variety of automobile shopper. This person, who does not own a car and so would have none to trade, goes around to a second hand dealer and gets a loan of a used car and a statement of the price for which he can buy it. He then takes the used car and goes shopping around to new car salesrooms, doing his best to trade it in for a new car at an allowance which will give him a considerable margin over the used car price fixed by the used car dealer.

This custom, which has become quite prevalent and which is depriving dealers of the few remaining prospects who made "clean" purchases, has had quite a demoralizing effect on retail sales conditions as a number of dealers have gone into the business of overbidding each other on an allowance for the used car.

## See Attempt to Put Over Burke Bill on Hoosiers

INDIANAPOLIS, July 20—Rumors that the State administration would attempt to duplicate in Indiana the Burke bill passed in Ohio this year, are being investigated by the Indiana Automotive Trade Association. It is said that the bill will be drawn for the State highway commission at the instance of Governor McCray and that it will be introduced in the "next legislature" with administration backing and steering it. This is taken to mean that Governor McCray will call a special session of the legislature this fall, for the "next legislature" would not convene until 1923, and preparation of a bill at this time would be premature unless there is some early prospect of a legislative assembly.

In conference with Tom Snyder, secretary of the Commercial Haulers Association, L. M. Shaw, general manager of the Indiana Automobile Trade Association, this week began formation of defensive plans to combat the effort of the administration, which is taken to mean that the administration does not intend to build up the State highways for modern traffic but hopes to meet the situation by eliminating the heavy duty equipment. Secretaries Shaw and Snyder propose to have a conference of all motor vehicle interests of the State with the State Highway Commission.

### ABANDON AVIATION MEET

DETROIT, July 19—The Detroit Aviation Society has decided to abandon the Pulitzer trophy and other events which were to have been held Sept. 8, 9 and 10 because it has been impossible to get assurances of entries by the army and navy.

## Garage Equipment Needed in Belgium

### U. S. Consul Reports Lack of Free Air Devices and Other Accessories

WASHINGTON, July 20—Manufacturers of automobile accessories will be interested in a report just received by the Bureau of Foreign and Domestic Commerce from James P. Moffitt, American Consul in Charge, Antwerp, Belgium, regarding the market for automobile air compression and garage equipment in that place. The report states that there are about 2500 automobiles, 500 trucks and 800 motorcycles in Antwerp. Of the 80 public garages, large and small, there are only about 30 important ones. The number of cars housed in a garage varies from five to 20, though the average number is more likely to be from 10 to 20. Garages in Antwerp, it is stated, do not equal American garages in size or efficiency.

Generally speaking, the equipment is not designed to save labor, but requires the least outlay and is confined to the absolute necessities. Garage equipment, as is used in America, it is pointed out, is not used in Antwerp, first, because it is not known, and, secondly, due to the small number of cars, garage owners go rather slowly in making investments. Labor always has been cheap, and time is not essential. However, due to the present high cost of labor, compared with prewar prices, it seems the opportune moment to introduce American garage equipment.

Only a few garages are equipped with mechanical air compressors, and there are no service stations which offer free air facilities from curb hose lines to the passing motorist. Two garages have systems from Luchard, Paris, whereby compressed air is stored in tanks and the tank is carried from one car to another to inflate tires. Smaller tanks are filled to be carried along with the car. Even this system is very expensive.

### CLOSE IMPORTANT CONTRACT

NASHVILLE, TENN., July 18—The signing of the final draft of the important contract between the Southland Motor and Body Corporation and the Nashville Industrial Corporation brings into existence the largest operation of this kind in the South. Reconstruction work on the big building leased by the company is under way and the company expects to make initial deliveries on orders the next sixty days. Representatives have been established in most of the southern cities to handle the direct sales to automobile agencies and garages. At the beginning the new plant will manufacture commercial bodies for Fords on contracts with large users such as mail order houses. The product will be known under the trade name of Old Hickory. About 150 people will be employed at the start.

## Col. Clifton Honored on 16th Anniversary

**Directors of N. A. C. C. Give  
President Painting in Recognition  
of Long Service**

BUFFALO, July 18.—In recognition of his sixteen years' service as a leader in the automotive industry, the directors of the National Automobile Chamber of Commerce to-day presented Col. Charles Clifton, president of the Pierce-Arrow Motor Car Co., with a handsome painting to be added to his private art collection. The picture was "Le Palais Rouge," a scene in Venice painted by Henri Le Sidanier.

The presentation was made at the Country Club in behalf of the directors and through them of the entire industry, by Alvan Macauley, president of the Packard Motor Car Co. The gift was deemed especially fitting at this time because Colonel Clifton was elected president of the N. A. C. C. for the eleventh successive term at the annual meeting in New York last month. The directors were in Buffalo for the monthly meeting, which has been held here once a year since Colonel Clifton became president.

In making the presentation, Macauley said that people usually wait until a man dies before they laud his efforts, but that in the case of Colonel Clifton his services to the industry had been so great and had extended over such a long period that it was considered a privilege to give him the painting as a token of appreciation for his valiant services.

Colonel Clifton had been a leader of the industry for sixteen years, Macauley said, and it was due largely to his able guidance that the industry had grown so rapidly from infancy to the leadership of all finished products. He described Colonel Clifton as "the father of co-operative competition."

## \$1,500,000 Tire Plant to Be Erected in Tampa

TAMPA, FLA., July 20—A tire and tube manufacturing plant, valued at \$1,500,000, will be built in Tampa in the near future by the Peninsula Tire and Rubber Co. The company has already been organized and the site for the factory, situated on the Atlantic Coast Line and Seaboard Railways just outside the eastern boundary of the city in a section known as Gary, has been purchased. A building two stories high, approximately 100 by 300 feet in dimensions, and having a floor space of 60,000 sq. ft., will be erected.

The construction will begin within 90 days and operation of the plant will start in about six months. One hundred tires and tubes a day will be manufacturing capacity of the plant in the beginning.

H. A. Van Auken has been named general manager of the new manufacturing concern. He was at one time sales manager for the Northland Rubber

Co. of Buffalo, N. Y., which was later absorbed by the Kelly-Springfield interests. He was also sales manager for the Mutual Tire and Tube Co., a co-operative distributing agency.

At the present time tires and tubes being sold by the Peninsula Tire and Rubber Co. are being manufactured under contract with the Doff Rubber Co. of Atlanta. The present contract will be continued until the new plant is completed.

## Capitalists To Back Making of Doble Car

SAN FRANCISCO, July 20—Backed by a number of capitalists of this city, and with Abner Doble, designer of the car, as a member of the corporation, an organization has been formed here to start construction of the Doble steamer, as soon as a factory site can be obtained. One of the first models, one that has run 57,000 miles with no sign of trouble to date, is on exhibition here. The directors of the new corporation are said to be prominent financially, and it is understood that no stock is for sale, and none will be offered, all having been taken by the men who have formed the organization. No names, other than that of Doble, have been made public as members of the corporation, but the announcement is generally regarded as reliable. Production of 500 cars a year is contemplated.

The Doble-Detroit Motors, Inc., was formed in 1916, but the War Industries Board ruled against it, and it dropped from active production after booking \$27,000,000 worth of business.

## Coast Firm Gets Large Tire and Tube Order

OAKLAND, CAL., July 20—The Coast Tire and Rubber Co. of this city announces the receipt of an order from a firm of distributors in Tokio, Japan, for \$53,000 worth of tires and tubes, including both fabric and cord tires in a variety of sizes. This is one of the largest orders ever placed by a Japanese house with an American tire manufactory.

This brings the total amount of tire and tube orders in the hands of this company up to an even million dollars, and additional machinery has been ordered for the local plant. Cities of Portland, Seattle and Spokane have ordered tires from this factory for their municipally-owned automotive vehicles.

## MAKING SPECIAL CAR IN SOUTH

SAN ANTONIO, TEXAS, July 20—The Robertson Co. has started the manufacture of an automobile especially adapted to Mexico. Texas and the Southwest. Specific claims are made for gasoline and lubricating oil economy and the design has been especially worked out for pulling on mountains, sand, rock and mud roads. It is understood that the factory is financed by Mexico and Texas capitalists.

## N.A.C.C. Seeks End of Insurance Evil

**Detroit Conference Will Hear Protests—Threaten Mutual Organizations for Nation**

NEW YORK, July 20—Vigorous protests against evils which have grown up in automobile insurance will be made by the insurance committee of the National Automobile Chamber of Commerce, headed by William E. Metzger, to the Automobile Underwriters Association at Detroit to-day. The underwriters will be told flatly that unless they take adequate steps to remedy these evils mutual companies will be formed in all parts of the country to take over the automobile business. Companies of this nature are already operated by the Automobile Club of America and by the Chicago Motor Car Co.

The N. A. C. C. committee has attempted for some time to co-operate with the underwriters, but has found that the co-operation on the part of insurance companies has consisted in counting up their losses for the previous year and doubling the rates. It is contended that the companies do not take the moral hazard into account in writing insurance and will give a notorious crook the same rate that is granted to a reputable business man.

Another evil of which complaint is made is over-valuation. Cars are now insured for such amounts that it is almost an incentive to destroy them.

Serious objections also will be raised to the demand of the Underwriters Laboratories at Chicago, which are maintained by the insurance company, that all materials which go into a manufacture of motor cars must be approved by the laboratories under penalty of being subjected to a higher rate.

## OSHKOSH TRACTOR TO MOVE

STEVENS POINT, WIS., July 18—The Farmers Tractor Corp., originally established at Oshkosh, Wis., has completed the transfer of its business and offices to Stevens Point, Wis., where temporary works have been opened pending the construction of a machine and assembling shop during the fall and winter months. A. J. Patch is vice-president and chief engineer. The company announces the appointment of Page, Beck & White, Inc., mechanical, automotive and industrial engineers, to act for it in a consulting capacity in matters pertaining to manufacturing plant, building and construction.

## COLEMAN TRACTOR IN COURT

KANSAS CITY, MO., July 20—Bankruptcy proceedings have been brought against the Coleman Tractor Co. by the following creditors, with amounts owing them: B-R Electric Co., \$30.59; Butler Mfg. Co., \$517.95; Bonniwell-Calvin Iron Co., \$1,688.88.

## 3622 Machines Sent Back from Overseas

Heavy Traffic for Fiscal Year—  
Exports Off Over \$33,000,000  
from 1920

WASHINGTON, July 21—Preliminary figures compiled by the Bureau of Foreign and Domestic Commerce for the fiscal year show that 3,622 American made motor vehicles with a value of \$5,789,163 were returned to this country without payment of duty. The number for June alone was 518 with a value of \$911,785. The records do not show what proportion of the reimportations were the result of cancellation of orders.

Imports of foreign made vehicles for June were 34 with a declared value of \$63,029 and the total for the year was 1,051 vehicles valued at \$1,264,108.

June exports of passenger cars were 1,964 machines valued at \$2,057,490. The total for the year was 84,430 with a value of \$103,786,970, a decline of \$21,598,055 in value from the previous fiscal year. Exports in June, 1920, were valued at \$14,486,362.

Truck exports for June numbered 418 machines valued at \$531,234, making a total for the year of 17,598 vehicles valued at \$29,511,955, a decline of \$12,065,729 from 1920. Truck shipments in June, 1920, numbered 2,697 valued at \$4,216,502.

Exports of automobile parts, not including engines and tires, for June, 1921, were valued at \$2,211,528. This was almost double the May, 1921, exports which were valued at \$1,171,071, with a total for the fiscal year of \$67,409,570, an increase of \$1,116,818 over 1920. Exports for June, 1920, however, were valued at \$7,429,188.

Total exports of automotive engines decreased in value \$10,784,195 to a total of \$23,526,568 for the year. There was a decrease for the year of \$5,747,689 in the value of tractor engine shipments.

### NEWS BULLETINS

DETROIT, July 21—To finance the production necessary to meet current orders, the Lincoln Motor Co. has arranged to issue bonds to the amount of \$2,500,000. Half of this issue already has been purchased by the directors of the company. This arrangement makes \$1,250,000 available immediately and leaves the other half of the bond issue in reserve for an emergency. The issue is secured by first mortgage on the fixed assets of the company. The same group of men is continuing its indorsement of all bank notes. Production is running at the rate of 300 cars a month and orders are highly satisfactory. More than two thousand Lincoln cars have been placed in the hands of owners in the past eight months. The inventory is being balanced and reduced and more than \$1,000,000

has been paid on trade acceptances since the beginning of the year.

TOLEDO, July 21—John N. Willys, who arrived here yesterday for a conference of the Willys-Overland factory, announced that the company would make "a very substantial payment" on its bank indebtedness on August 1. The company now has \$10,000,000 in cash, he said, and its bank obligations total only \$20,000,000. Willys said there would be no further reductions in price of Willys-Overland cars.

NEW YORK, July 21—The Netherlands Aircraft Mfg. Co., of Amsterdam, Holland, controlled by Anthony G. H. Fokker announces that it soon will begin the manufacture of Fokker 'planes of all types in this country.

NEW YORK, July 21—The Federal Reserve Bank of New York has reduced its rediscount rates from six per cent to five and one-half per cent on all classes of eligible paper. The reduction is the third this year from the peak rate of seven per cent. The five and a half per cent rate also has been established by the reserve banks of Boston, Philadelphia and San Francisco.

## Delay Refinancing of the Willys Companies

NEW YORK, July 18—Refinancing of the Willys-Overland Co. and the Willys Corp. has been delayed by the reluctance of the preferred stockholders to give their assent to the issuance of mortgage bonds. One of the provisions in all the Willys preferred stock is that the consent of 75 per cent of the holders must be obtained before any securities can be issued. The bankers committees will issue a report this week telling of the progress which has been made, but it will make no reference to the tentative plan agreed upon. Notwithstanding the delay, it is certain that the financial affairs of the companies eventually will be worked out in a satisfactory manner.

The Willys-Overland Co. is making a highly satisfactory sales showing and the same is true of the Electric Auto-Lite Co. The New Process Gear Corp. also is receiving substantial orders. It is understood that when the reorganization and refinancing are worked out, the big Elizabeth plant, now a part of the Willys Corp., in which the "Chrysler Six" will be built, will be a separate unit, although there will be no change in its control.

## Report Says Ford Will Cut Cars in England

LONDON, July 8 (By Mail)—The outstanding automobile event of this week is the further reduction of Ford prices and the report current in inner trade circles that a further drop is impending. The present price of the Ford touring model is \$1,100 (at pre-war rate and the price reported as likely to follow would reduce it by a further \$100 to \$200.

## Reorganization Plan for Mercer Motors

Purchasers Found For Bonds If  
Creditors Take Notes for  
80% of Claims

NEW YORK, July 21—After months of laborious effort, the committees representing bank and merchandise creditors have evolved a satisfactory plan for the reorganization of the Mercer Motors Co. This plan has been accepted by the representatives of both classes of creditors.

As a preliminary it calls for an agreement with the officers and directors of Hare's Motors, the selling organization, for the cancellation of all contracts and options. The committees have expressed formally their appreciation of the helpful attitude of Hare's Motors and it is recognized that general conditions rather than lack of ability on the part of the executives were responsible for the difficulties of Mercer.

Purchasers have been found for \$500,000 of first mortgage bonds, which will provide working capital, contingent upon the issuance of \$2,000,000 in sinking fund collateral notes bearing 7 per cent interest, which both bank and merchandise creditors would be expected to accept for 80 per cent of their claims. If the creditors agree to this proposal they will be paid 20 per cent of their claims on Aug. 1 or as soon thereafter as possible and an additional 5 per cent before Dec. 31. The notes would be secured by the assets of the Simplex Automobile Co., Inc., and 50 per cent of the net earnings of the Mercer company would be paid over to a trustee for the benefit of creditors.

The purchasers of the bonds would insist upon the resignation of all the present officers and directors and the right to elect a new board as well as a release from the contract with Hare's Motors.

It is proposed to redesign the Mercer car and get it on a commercial production basis of 30 cars a month this year and to double that output in 1922.

A letter will be sent this week to bank and merchandise creditors of the Locomobile Co. asking them for an extension of time, probably for six months, in the hope that by the end of that period some plan can be evolved for the reorganization of that company. If an extension is granted it is believed this can be done.

## Goodyear Has Best Week in History of Company

AKRON, OHIO, July 18—Goodyear Tire & Rubber Co. dealer sales for the week ending July 16 were the largest in the history of the company, officials report, with sales to dealers of more than 72,000 complete tire units. Tire stocks are low, according to expert analysts, and present indications point to a shortage of tires if the present rate of buying keeps up, unless all manufacturers at once increase production.

# No Entangling Alliance for Durant

## Mergers Not Planned Stockholders Told

### Statement Says Company Does Not Intend to Monopolize Industry

NEW, YORK, July 20—Most of the innumerable rumors about the ultimate plans of W. C. Durant are set at rest by the definite statement of policy contained in a statement which will be mailed this week to stockholders of Durant Motors, Inc., outlining the progress made thus far in developing the enterprise. In this connection the statement says:

"Durant Motors, Inc., was not organized for the purpose of monopolizing the motor car industry or effecting a combination, merger or consolidation of existing companies in either motor car or accessory lines, and, regardless of rumors to the contrary, will consider no combination, mergers or entangling alliances with any firm or corporation identified with the production of automobiles at this or any future time.

"Durant Motors, Inc., was organized to build a line of popular priced motor cars designed by Mr. Durant, the business owned by Mr. Durant and his close associates, with no partner other than the investing public."

This disposes of the popular belief that Durant is building up his new enterprise with a view to selling out to the General Motors Corp. when it is built up to the right proportions. It also settles the report that he has acquired a very substantial interest in the Studebaker Corp. in the expectation of merging that company with his.

It can be stated, however, that the proceeds of sales of Durant stock are working and earning dividends. In fact, it is understood that the investments made have been so profitable that it would be possible at this time to pay a dividend on all Durant Motors stock which has been sold.

In addition to these statements in regard to policy, the letter to the stockholders says:

#### The Durant Statement

"Since its organization in January, 1921, three companies have been incorporated and are being independently financed to assemble the Durant line of popular priced cars. These are:

"Durant Motor Co. of New York.

"Durant Motor Co. of Michigan.

"Durant Motor Co. of California.

"Each of these companies, with respect to policy, product, operating and sales, will be controlled by Durant Motors, Inc. The parent company will be responsible

for and assume all engineering expenses in addition to providing proper and dependable sources of material supply. For this service and the use of patents, inventions, name, etc., Durant Motors, Inc., is to receive a major participation in the profits.

#### Will Produce in August

"Durant Motor Co. of New York, capitalized at \$3,000,000, will assemble the Durant car at Long Island City for distribution in the Atlantic Coast territory and export markets. The plant has a capacity of 25,000 cars a year and will be in production next month. F. W. Hohensee, president and general manager of the company, was formerly in charge of the operation of the entire group of Chevrolet factories.

"Durant Motor Co. of Michigan, capitalized at \$5,000,000, with headquarters at Lansing, Mich., is building in that city a modern plant with a capacity of 40,000 cars a year. The building contract specifies completion by November 1 next. E. Verlinden, who has been responsible for the development of the splendid business of the Olds Motor Works, is president and general manager of the Michigan company, which will assemble and distribute the Durant car in the territory between the Adirondacks and Rocky Mountains.

"Durant Motor Co. of California, capitalized at \$3,000,000, has secured an excellent location at Oakland, Cal., and plans are now being drawn for a modern plant having a capacity of 20,000 cars a year. Construction work will go forward on a schedule to permit automobile production in March, 1922. R. Clifford Durant, who until recently was at the head of the Chevrolet Motor Co. of California, is president and general manager of this company, which will assemble the new Durant car for distribution in the Pacific Coast territory.

#### Get Another Plant

"In addition to the above:

"Durant Motors, Inc., will on August 1, 1921, come into possession of the splendid plant in Muncie, Ind., now being operated by the Sheridan Motor Car Co. Division of General Motors Corp. A new company to be known as Durant Motor Co. of Indiana, capitalized at \$3,000,000, will be organized for the purpose of manufacturing at Muncie an exclusive six-cylinder car to sell at a popular price. D. A. Burke, formerly manager of the Chicago branch of the Buick Motor Co., will, as president and general manager, direct the affairs of the new operating company."

When Durant comes into possession of the Sheridan plant the name of the car will be changed to the "Durant Six."

## Deny Sale of U. S. Cars at Cut-Rate Prices

### Official Report Says Ex-Service Men Are Not Getting Machines Cheaply

WASHINGTON, July 20 — Official denial was made to-day to reports that the War Department had changed its policy of selling surplus motor vehicles by offering for sale, in blocks of ten, Ford runabouts and touring cars at nominal figures. The statement that trucks and touring cars are being sold to men in the service and ex-service men at cut rate price and that trucks are being leased for one hundred dollars per year, were branded as erroneous. The official statement reads:

"The only motor vehicles available for sale at this time are unserviceable ones. Under acts of Congress all serviceable automobiles not required for the use of the army are transferred to other Government departments to meet their requirements. The unserviceable cars—those not desirable by any other department—are offered to the public at public auction. Less than 10,000 unserviceable motor vehicles had been sold to July 9, 1921. More than 42,000 serviceable cars had been transferred to other Government departments up to that date.

"The records show that to July 3, 30,303 automobiles had been transferred to the Public Roads Bureau, Department of Agriculture, the Post Office Department had requisitioned 8286, the Public Health Service 1565, the Engineer Corps River and Harbor Works 305, and the Navy and Marine Corps 1273.

"A total of 51,444 motor vehicles had been disposed of to July 9, to which 41,955 had been transferred to other Federal bureaus."

#### TIRE PRODUCTION 70,000

AKRON, July 19—Tire production in this city now exceeds 70,000 which approximates 60 per cent of capacity for all factories. Goodyear is making 24,000 a day. Firestone 21,000, Goodrich 15,000, Miller 4,500 and the smaller companies a total of about 7,000.

#### DETROIT EMPLOYS 4,333 MORE

DETROIT, July 18—Reports from the 79 members of the Detroit Employers Association for the week ended July 12 showed 113,181 men on the payrolls, an increase of 4,333 over the previous week. There were 14,782 workers on part time, however, as compared with 9,251 the week before. Ford Motor Co. is running at full speed and contemplates a July production of 109,000.

# Export Trade Shows Improvement

## Business Increases in Foreign Fields

### Export Lists Show General Improvement in June—Automotive Trade Leads

NEW YORK, July 19—Business conditions in many of the foreign countries making up the export lists of the American automotive companies showed general improvement during the month of June, according to the monthly cables received by the Bureau of Foreign and Domestic Commerce from its trade commissioners and commercial attaches in the larger capitals of the world. This was especially true in Australia, China, France, Great Britain, Germany and South Africa.

#### Demands in Spain

Of special interest to the automotive trade is the dispatch from Commercial Attache Cunningham at Madrid that the demand in Spain is reviving and sales increasing of American automobiles, accessories and equipment, despite the fact that the Spanish markets are generally overstocked. Likewise of concern is the statement, dated July 5, from Singapore that German motor trucks are selling steadily in the Dutch East Indies. Aside from this indication of activity, Trade Commissioner Fowler declares that business is very dull and that there is little demand for imported commodities.

Little change in regard to other countries is reported. The process of deflation is continuing, but slight improvement is recorded by the trade observers.

The financial situation in Australia is reported as having shown some improvement, despite the decline in exchange and stocks of import merchandise have been reduced somewhat, resulting in inquiries being renewed in some lines. Commissioner Farin believes that wholesalers may begin buying again after the stock taking and closing of the fiscal year on June 30.

#### Chinese Outlook Better

The Chinese trade outlook is stated to be better than at any time during the last year. With less speculation in silver, the financial situation is improving and June settlements on the Shanghai stock exchange were the most encouraging since the armistice. Activity in highway and road construction is reported in North China.

Unrest and strikes have increased in Japan and money has become tighter, although bank loans have increased. No transactions of any importance are reported from the Straits Settlements and business remains at a standstill.

Trade Commissioner Butler, however, describes increased activity from Paris, where many new loans are being authorized for purposes of reconstruction and improvements. The labor situation is said to be growing more satisfactory. French war stocks have been liquidated to the value of 6,000,000,000 francs, leaving about 750,000,000 yet to be cared for. It is estimated that 18 months will be required for the complete liquidation of all French and American army supplies.

The financial and industrial situation in Germany has improved and checking and savings accounts in the banks are increasing. Unemployment is decreasing and great betterment was shown in June in the boot and shoe, clothing, cotton spinning and woolen goods lines.

The crisis of the readjustment will not be reached in Italy before August or September, it is stated, and unemployment is decreasing, although there seems to be less tendency toward unrest and industrial strikes. The depression in trade and finance in Scandinavia shows no signs of improvement, although deflation is occurring and speculation is decreasing.

#### Optimistic Feeling

Contrasted with this, however, is a general feeling of optimism in England. This is due to the reduction of the bank rate and the settlement of the coal strike. Prices of cotton, silk, hides, foodstuffs and flour showed some tendency to strengthen during the latter part of June but the prices of wool, flax, jute, sugar, coffee, wheat, oil, rubber, copper, tin and iron weakened. Settlement of the engineering trade wage dispute relieved a grave industrial situation. All of which brings forth the comment that the British industrial situation presents a bright aspect.

Argentina was reported in about the same condition as in June. There has been a notable improvement in the labor situation.

## British Automobile Makers Will Convene

LONDON, July 1 (By Mail)—A conference of British automobile makers and British automobile dealers throughout the world is fixed for the latter part of the month. The conference should do something to explain to British automobile makers why they have lost so much ground overseas. Other nations have the labor evil factor to contend with, and beyond all there is the fact that American labor is paid at a higher rate, apart from the workers' earning and being able to earn more than the British worker, yet produces and sells so much cheaper and having 83 per cent of the world's trade. This is one of the problems the conference needs to solve.

## Ford Sales Multiply in Peruvian Cities

### A. C. Shumway Opens Branches in 11 Cities—See Good Chance for Higher Priced Cars

LIMA, PERU, June 30 (Special Correspondence)—Two features in the automotive market of Peru have become prominent in the last year, although in a certain manner they are contradictory to each other. The first development in Peru is the extensive plan formed for the marketing of Ford automobiles, trucks and tractors.

The Ford representative in this country, A. C. Shumway & Co., with head offices here and from which it also handles the business in Callao, has opened branches and sub-agencies in eleven other cities and towns. The branches are at Pisco, Ica, Chincha, Trujillo, Chiclayo and Huancayo and the sub-agencies at Canete, Huacho, Supe, Piura and Pacasmayo. These localities range in population from 4000 to 22,000. Many of them are seaports, but each is the center of a rich agricultural or mining territory which heretofore has not been properly represented by automobile dealers and service stations. The Shumway branches will handle only Ford products and do Ford service work.

#### Right in Market

Automotive manufacturers and sellers of automotive products should watch these places and get in touch with dealers in the same cities. These places are now markets for Ford parts, tires and accessories. Soon, that is within a year or a year and a half, these localities will be markets for higher priced cars than the Ford.

The second development is the arrival of European cars. There are now to be seen in Lima the Fiat, Renault, Daimler, Benz, Opel, Wolsley, Mercedes and Minerva.

#### Trucks and Tractors

The Fiat and Renault agents have trucks and tractors as well as automobiles. The Daimler has a truck but no tractor. The Daimler, to which reference is made, is an English product. Curiously enough, there is a truck by the same name manufactured in Germany and several of them are in use in Lima. In addition to the German Daimler there is a Bussig, a French DeDion Bouton and a Draga, a Scotch truck. The Fiat, Renault and Daimler are the only companies seriously represented. The other makes are for the most part direct importations by consumers.

## Dallas Shows Gain Over June Business

### 10 to 15 Per Cent Increase in First Ten Days, Dealers Declare

DALLAS, July 20—Canvass of 15 retail automobile concerns in Dallas revealed that sales during the first 10 days of this month showed an increase of from 10 to 15 per cent over sales for the same period in June. Dealers declare this is due to the fact that the marketing of grain crops is pouring some \$30,000,000 into the pockets of the grain growers and as this money finds its way into other channels, financial stringency is loosened up and cars are bought.

The same retail houses declare prospects now are better than they have been in many months and say they expect to do a banner business during July and August. Another cause of increased sales is said to be the season for touring. Reduced prices were a decided factor in increased buying.

In addition to retailers reporting increased sales for the first 10 days of July, the used-car dealers declare they have never had better business. Retailers claim they are having more inquiries for cars right now than they had for a year and that generally these inquiries lead to sales.

Accessory and tire men also reported improved business during the early part of July. It is learned from wholesalers here that the automobile business over the territory generally is improving and that sales have increased during July.

### Denver

(Continued from page 136)

ness about further price drops, though some dealers report slower business. One dealer has sold six cars in July against 18 for the first half of June, but he had a rush then because the June 1 price drop attracted waiting buyers. He is now short on certain models demanded and also says July always was a slow month.

Another dealer reports 12 cars sold in July at retail against only three in June for the same period. This dealer believes that price restlessness largely has been overcome and another distributor expects his July total to exceed June sales of 44 at retail and wholesale.

Exact registration comparison is impossible because no July licenses are yet entered on the State records but leading dealers lean toward a slight gain.

### Atlanta

ATLANTA, July 20—Automobile business as a whole is less so far in July

than in June for the same period. Companies reducing prices July 1 are experiencing a good increase, but there has been a considerable falling off in sales of those cars reduced June 1. Ford sales are reported exceptionally brisk. Recent reduction in discount rates of the Federal Reserve Bank of Atlanta does not appear to be having any effect on sales. Continued low price of cotton is seriously affecting all lines of business and sales of automobiles to farmers as a result are far below normal.

It is too early in July to give an accurate comparison with June business, but as a whole dealers say business has been experiencing an upward trend in the past two or three months. This is exclusive of the stimulation caused when price reductions were announced.

### Louisville

LOUISVILLE, KY., July 20—As the season progresses, automobile sales are increasing rather than falling off, according to opinions of leading automobile dealers here.

Outstanding facts seem to be as follows:

The number of new purchasers of new cars is steadily increasing. That is, the number of persons buying cars who have never owned cars, and have not in consequence any "trade-ins," is increasing. This is particularly encouraging to the dealers, since the main end of the business must always be the sale of new cars. Price reductions, which have been on practically every make of automobile sold in Louisville, have established the market and created a new demand for automobiles.

On high priced cars, business, while apparently slow, is shown to be normal for this season of the year by a comparison with the last five years. The reason this class of cars moves slower now than during the spring and fall seasons is that purchasers of high-priced cars are away from the city during practically all of the summer.

### New Orleans

NEW ORLEANS, July 20—Four out of five largest local dealers say the first part of July sales are under for the same period in June when business was stimulated by price reductions. The Dodge distributor sold 95 cars in June and is doing about 60 per cent of this business in July. United Motor Car Co., Peerless distributor, reports very light July business.

Capital City, Studebaker dealers, report sales about one car per day, slightly under the June rate. Bernstein Glenny Co., Buick distributor, reports total sales for spot and future delivery and used cars in excess of June. Cadillac reports about 50 per cent of June business.

## Production Figures Sought by Nation

### Director of Census Calls Conference of Representatives of Automotive Industry

WASHINGTON, July 18—Director of the Census Stewart will hold a series of conferences with representatives of the automotive industry and other large trade and craft organizations to discuss the manner and methods for collecting and publishing production statistics for 1921. The meetings will be under the auspices of the National Association of Manufacturers, although non-member organizations will participate, because it is purely a Government conference.

Secretary Hoover has given directions to the Director of the Census to collect current commodity statistics under the provisions of Section 8 of the act of Congress of Feb. 14, 1903, which authorizes the secretary to make such special investigations and reports "which he, himself, may deem necessary and urgent." The primary design of this conference, the association has announced, is to determine the character and form of the schedules to be used in the collection of the census of 1921, which work begins Jan. 1, 1922, and to relate such work to the collection of such current commodity statistics as are desired by the Secretary of Commerce and which may be useful to the industries of the country.

The conference will be of the same general character as that assembled by the National Association of Manufacturers at the invitation of the Director of Census in 1919 and which proved of such value as to call for commendation of the director in the annual report for the year 1920.

President Edgerton will promptly issue a call for the conference which, it is stated, may result in the working out of a method of direct co-operation between trade and craft organizations with the Bureau of the Census, whereby they may collect for and on behalf of the census and themselves the figures relating to their industry.

### Toledo

TOLEDO, July 20—Automotive dealers here believe that the buyers' strike, as far as it effects automobiles and accessories, has been broken.

The retail sales here show that to be the fact. Every dealer made a record during the month of June, and sales are continuing well this month.

The lowering of prices has demonstrated that people have had the money to buy but were waiting. Toledo dealers have been amazed with the amount of cash business they got these days. In the last six months or more nearly 80 per cent of the automobiles sold here have been on payment plans.

## Chevrolet Prices Cut Second Time

### Reductions on All Models, Effective July 15 Announced in Detroit

DETROIT, July 20—Another reduction in prices on all models in both its lines has been made by the Chevrolet Motor Co., effective July 15. In the "FB" line the touring car and roadster have been cut from \$1,185 to \$975 and the coupé and sedan from \$1,885 to \$1,575. On the "490" models, the touring car has been reduced from \$645 to \$625; the roadster from \$635 to \$625; the sedan from \$1,195 to \$975 and the coupé from \$1,155 to \$975. The prices are f.o.b. factory. This is the second of the General Motors Corp. subsidiaries to make a second price reduction since the readjustment began. The Oakland led the way.

### KISSEL MAKES SECOND CUT

HARTFORD, WIS., July 20—A second reduction in prices is announced by the Kissel Motor Car Co. The standard touring car is reduced from \$2,775 to \$2,475, a total cut of \$1,000 since the price readjustment began. The following reductions are made on the "de luxe" models: Speedster and touring car, from \$3,475 to \$2,975; coupé and sedan from \$4,275 to \$3,775. This makes a total reduction of \$800 on all the "de luxe" models.

### FORD CUTS FREIGHT RATES

COLUMBUS, July 18—The Detroit, Toledo & Ironton Railroad, owned by Henry Ford, has filed with the Public Utilities Commission new freight rate schedules making a general reduction in freight rates on the road 20 per cent, to become effective August 2, if the commission approves.

Before Mr. Ford's road can apply reduced freight rate to interstate traffic it will have to file them 30 days in advance with the Interstate Commerce Commission, which may suspend their effectiveness pending investigation if it sees fit. In view of what Chairman Clark has recently said about a general reduction, railroad men think the commission will not approve one at this time.

### WANT LOWER RUBBER RATE

NEW YORK, July 18—A hearing will be given by the Consolidated Classification Committee, which represents all railroads throughout the country, on the request of the traffic committee of the Rubber Association of America for a reduction in all territories of the carload rating on crude rubber. The committee wants the rating taken from the fourth class and to the fifth.

### BUYERS GET NEW ROADSTER

DETROIT, July 18—The Wills Sainte Claire roadsters are now in production

and the cars of this model are already getting into the hands of purchasers. The roadster body is mounted on the standard chassis with a wheelbase of 121 in. The roadster seats two in the front seat and two more in a rumble seat.

The standard colors provided are Lady Mary maroon, Newport blue and Liberty green. The radiator, hub caps and side or courtesy light are nickel plated on the roadster. Like the touring car, the roadster is equipped with disk wheels painted to correspond with the body. The price of the roadster is \$3,275 f.o.b. Marysville. This is \$75 more than the touring car. Coupé and sedan bodies for the Wills Sainte Claire line are now under construction and will shortly be on the market.

### Lansing Plant of Reo Reopens on Schedule

DETROIT, July 18—The Reo Motor Car Co. of Lansing, which closed July 2 for two weeks, reopened to-day on schedule and is operating in all departments. R. C. Rueschaw, sales manager, said that the simultaneous vacation plan which was tried out this year for the first time apparently has been highly successful and unless unexpected opposition develops it probably will be adopted permanently. The trial of the plan by Reo has been watched with interest by several Detroit companies and in view of its success its adoption is likely to become widespread. The opportunity given for plant repair and for a general clean-up of all the production departments is said to have many advantages. Reo has resumed on a full time schedule.

### SUE VERLINDEN IN NEW YORK

NEW YORK, July 18—The General Motors Corp., which recently brought suit in Michigan to recover from Edward Verlinden approximately \$500,000, which he is alleged to have obtained wrongfully by cashing a check made out in his favor while at the head of the Olds Motor Works, has brought a virtually identical action in the Supreme Court of this State on the theory that he has large property holdings in New York. Verlinden's friends deny, however, that he owns property here.

### TRAILER FIRM WILL GO ON

EDGERTON, WIS., July 18—The Highway Trailer Co., Edgerton, Wis., intends to begin work within a few days on the reconstruction of its main shop building, which was almost totally destroyed by fire on the night of July 4, causing a loss estimated at \$260,000, with insurance of about \$90,000. Work has been delayed somewhat in order to enable officials of the company to determine the responsibility, if possible. At the request of the concern, the State fire marshal's office is making an investigation of cause. The building was 190 x 875 ft. in size, part two stories, of solid brick, with mill roof trusses and concrete floors.

## METAL MARKETS

IN judging whether continuing reports of price cutting in the steel market are based on facts and whether the recently downward revised schedules of the chief interest and the leading "Independents" will once more deteriorate into a nominal list observed solely as a means of cutting under, the automotive purchasing agent must exercise extreme caution. As on previous occasions, a large number of steel producers look once more to the automotive industries to set the wheels of representative demand in motion. As far as can be positively ascertained, there has been no price cutting on fresh inquiries. When the Bethlehem and United States Steel corporations promulgated their new schedules some business was in process of negotiation at lower levels than those which these interests announced, and it is these figures which came to light recently and were forthwith interpreted as fresh evidence of a repetition of the previous situation in which "official" prices were gradually undermined by the intensive contest for what little business the market offered. Then, again, there are still innumerable resale transactions in which prices considerably lower than for "production" steel prevail. A Chicago automotive instrument maker offered a few days ago from his surplus free cutting cold-drawn steel at \$2.50 cwt. base and hot-rolled strip steel at \$2.25 cwt. base, as compared with \$2.80 and \$2.50 asked by producers. The price named by this reseller for cold-rolled strip steel, however, was \$4.25 cwt. base, which is also the producers' price. There has been a good deal of talk about certain sheet mills cutting \$5 per ton under the "official" price. This appears to be the result of confusion, certain mills having based prices for certain gauges of sheets on the plate schedule. Buyers are testing the market in every conceivable manner. A bid of \$30 for a 500-ton order of sheet bars is a case in point. As stated before, further downward revision of steel prices waits upon two factors, lower freight rates and further downward adjustment of wages. Progress is being made in the latter direction, but as for the former there is still no indication when relief may be expected. There is, therefore, little likelihood of a further cut in "official" prices in the immediate future. Market news is scarce in the dog-days, and it is only natural that there will be frequently recourse to speculation as to when the next change in prices will come. Meanwhile, however, there is a slow but nevertheless perceptible improvement in activities, especially of the smaller mills.

**Pig Iron.**—Automotive foundries are taking on larger tonnages, especially so because prices are thought to have reached levels at which all risk is eliminated.

**Steel.**—So far the principal activity in the market for cold-drawn steel bars consists of releases from passenger car builders, with fresh business confined to small tonnages for filling in purposes. The leading builder of low-priced passenger cars is reported to have placed additional orders. Cleveland reports have it that an order for 10,000,000 bolts is about to be placed by a Detroit automotive interest. Most of the sheet business coming out is for less than carload tonnages.

**Aluminum.**—The Aluminum Co. of America has reduced its base prices, making 98 to 99 per cent virgin ingots 24½ cents, No. 12 alloy 23.80 and sheets 39.10. As a result of this reduction the entire outside market is unsettled and lower.

**Copper.**—The market is flat and domestic demand conspicuous by its absence.

**Tin.**—At present prices tin is considered cheap, and some consumers are buying moderately because they consider values advantageous.

## FINANCIAL NOTES

Velle Motors Corp., in a comparative balance sheet of Dec. 31, shows assets for 1920 as \$7,729,930, as compared with \$5,478,529 for 1919. Cash on hand for Dec. 31 is shown as \$94,550, against \$104,293 for the previous year. Notes receivable are \$76,594, and the year previous \$5,400. Accounts receivable are \$564,301, while the year before they were \$666,057. Inventories total \$4,686,805, while in 1919 the sum was \$3,234,105. The company's liabilities show a gain. The figures for 1920 are \$7,729,930 and for 1919 \$5,478,529. Notes payable in the new balance sheet come to \$1,787,911. In 1919 they were \$400,000. Accounts payable are \$517,135, against the old figure of \$470,379. Other figures are: Profits discounted, 1920, \$449,592; 1919, \$387,949; surplus, \$706,178, 1920; \$1,884,970 in 1919.

International Motor Truck Corp. profits for April were \$108,000, for May \$150,000 and for June \$250,000. For the first half of the year they approximated \$500,000. This will not cover preferred dividends for that period, but it is an exceedingly good showing for a time of acute depression. Plants are being operated at about 70 per cent of capacity. The company has reduced its inventory \$3,000,000 since the first of the year, it has no bank loans and about \$3,000,000 in cash.

Peerless Truck & Motor Corp., in a comparative balance sheet filed Dec. 31, 1920, shows calls of \$14,919,065, as against \$12,928,601. The net income is \$1,063,306, as compared with \$670,628 in 1919. The assets are \$13,854,667, against \$15,651,529. Inventories, 1920, \$5,410,080; 1919, \$3,918,767. Cash, 1920, \$421,312, against \$1,327,043 in 1919. The surplus in 1920 is \$5,603,557, against \$5,259,800 for 1919.

Wire Wheel Corp. of America, in a comparative balance sheet filed Dec. 31, shows assets in 1920 of \$6,121,305, against \$6,239,580 for 1919. Accounts receivable are \$229,725, against \$336,889; notes receivable, \$54,984, against \$2,713; inventories, \$1,395,883, against \$1,049,587; cash, \$142,644, against \$624,662. Notes and accounts payable, \$398,722, against \$186,417, and surplus, \$1,563,686, against \$528,103.

Root & Van Dervoort Corp., in its 1920 comparative balance sheet, shows assets of \$7,777,984, with cash of \$631,932; receivables, \$896,360; inventories, \$3,811,917; deferred charges, \$39,052. Notes payable come to \$3,328,550. Surplus shows \$1,466,792.

Franklin Automobile Co. on June 28 paid off the last of its bank borrowings, which on Dec. 31, six months ago, amounted to \$4,510,000; on Aug. 31 of last year, when the Franklin inventory reached its peak, bank loans amounted to \$4,785,000.

Merrill, Lynch & Co. and Cassatt & Co., are heading a syndicate for the sale of a new issue of \$1,500,000 Spicer Manufacturing Corp. ten year 8 per cent. sinking fund gold bonds, due July 1, 1931 at 99 and interest.

American Motor Body Co., in a financial statement for 1920, shows assets of \$23,153,028; accounts and notes receivable, \$1,191,416; cash, \$2,002,854; notes payable, \$322,500; accounts payable, \$898,371; surplus, \$269,457.

Kelly-Springfield Tire Co. announce a quarterly dividend of \$2 per share on the 8 per cent preferred stock of the company payable Aug. 15, 1921, to stockholders of record Aug. 1, 1921.

Motor Products Corp. has declared a regular quarterly dividend of \$1.25 a share on the Class "A" stock, payable August 1 to stockholders on record July 20.

Mullins Body Corp. has declared a regular quarterly dividend of \$2 a share on the preferred stock, payable Aug. 1 to stockholders of record July 23.

Hood Rubber Co., declared the regular quarterly dividend of \$1.75 on preferred stock, payable August 1, to stock of record July 20.

Hale & Kilburn Corp., in a comparative balance sheet for 1920, show assets of \$4,632,091, against \$7,517,637 for 1919.

New Rotarian Will Make  
Transcontinental Run

HOBOKEN, N. J., July 20—The first Rotarian car to be manufactured by the Bournonville Rotary Valve Motor Co. will be given a transcontinental test run under the supervision of the American Automobile Assn. The engine, which has the Bournonville rotary valve, is the feature of this car and, during the test, the valve mechanism will be sealed. The valve will be calipered before and after the run to show that wear is negligible.

With the exception of the engine, the new car is assembled of standard parts. The important units are as follows: Columbia axles front and rear, Borg & Beck clutch, Brown Lipe gearset, Arvac propeller shaft and Parish & Bingham frame. The body work and equipment will be of the highest class and it is anticipated that the complete car will sell for approximately \$5,000. It is believed that these cars will serve to introduce and popularize this type of engine. Later it is intended to license the manufacture of this type of engine.

International Closes  
Its Springfield Works

SPRINGFIELD, OHIO, July 19—After keeping up above its schedule on light motor trucks for several months and slowing down for the past few weeks the Springfield works of the International Harvester Co. closed Saturday. Those identified with the company stated that the suspension of operations is due to a general slump in the motor truck business. They expect to see business forge ahead again in the early fall. Just when the works will resume operation is uncertain, it is stated.

Newmark Appointed  
Hawkins's Assistant

DETROIT, July 20.—J. H. Newmark, who for the past five years has been advertising manager of the Chevrolet Motor Car Co. in New York, has been appointed assistant to Norval Hawkins, who is on the advisory board of the General Motors Corp. in Detroit. Newmark has taken up his work in Detroit with his office located in the General Motors building. Newmark has been twelve years with General Motors companies, having served one year with Oldsmobile; six years with the Oakland Motor Car Co. and five with Chevrolet. Previous to his association with the Chevrolet company he was with Apperson Motor Car Co. in Kokomo, Ind.

## BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES by the Guaranty Trust Co., second largest bank in America.

During the past week gold reserves of the Federal Reserve System increased \$14,738,000, and total reserves \$16,383,000. Bills discounted secured by Government obligations decreased \$55,593,000, while other bills discounted decreased \$41,790,000. The total bills on hand, July 13, were \$1,729,115,000 against \$1,832,499,000 the previous week. Total earning assets decreased \$95,913,000 to \$1,999,622,000. Total deposits decreased \$19,161,000 to \$1,693,991,000, while note circulation declined \$68,083,000 to \$2,608,803,000. As a result of these changes, the ratio of total reserves to deposit and Federal Reserve note liabilities combined, increased from 60 per cent on July 6 to 61.6 per cent on July 13, while the ratio of gold reserves to Federal Reserve notes in actual circulation, after setting aside 35 per cent against deposit liabilities, increased from 76 per cent to 78.9 per cent. Of the reduction in note circulation of \$68,000,000, the New York Reserve Bank contributed over \$30,000,000.

Money rates showed a slight tendency to rise during the week by reason of heavy Government withdrawals, necessitated by the retirement of \$132,886,500 5½ per cent certificates of indebtedness and the mid-month corporation disbursements. Call money ranged between 5½ per cent and 6½ per cent as against a range of 5½ per cent to 6 per cent in the previous week. Commercial paper rates for 60 to 90 days remained stationary at 6¼ per cent to 6½ per cent for the best grades, with quotations of 6½ per cent to 6¾ per cent for others, but the volume of transactions was comparatively light. Time money for all maturities up to six months was at 6 per cent, rising to 6½ per cent at the end of the week. There was no change during the week in the re-discount rates.

Wholesale prices for June, as indicated by the index number of the Bureau of Labor Statistics, continued to decline but at a relatively slower rate than for any previous month during the last year with the exception of May. The all-commodities index now stands at 148 against 151 for May and 154 for April. This represents a decline of 2 per cent compared with a decline of 1.9 per cent in the previous month. The rate of decline has shown a steady tendency to slacken since the maximum month's decline of 8.7 per cent in last December. Among the individual indexes, that for farm produce, which rose from 115 in April to 117 in May, declined to 113 in June. The food index dropped one point to 132 as also the cloths and clothing index which is now 180. The house furnishing goods index, which is at present the highest, declined from 262 to 250. The index for fuel and lighting declined from 194 in May to 187 in June, and that for metals and metal products from 138 to 132.

## MEN OF THE INDUSTRY

Walter C. Lindemann, M. E., of the A. J. Lindemann-Hoverson Co., Milwaukee, was elected president of the Milwaukee Engineers' Society at the annual meeting. He is 34 years of age and a graduate of the University of Wisconsin and the Imperial Engineering University at Charlottenburg. Arthur Simon, of the Cutler-Hammer Mfg. Co., was elected vice-president; Fred H. Dörner, power plant manufacturers' representative, secretary, and Albert Blatz, Jr., president Standard Separator Co., treasurer. Trustees for three years are: M. A. Beck, Milwaukee Electric Crane & Mfg. Co.; Harold Falk, general superintendent Falk Corp.; Herman Schiffin, Allis-Chalmers Mfg. Co.

Rudolf Hokanson, vice-president and general manager Nash Sales Co., Milwaukee, distributor of the Nash line, and his brother, Emil Hokanson, president of the Wisconsin Oakland Co., distributor of the Oakland, accompanied by their wives, depart July 25 from New York on the steamer Paris for Le Havre, to spend about three months in touring Europe. They will visit the battlefields and then proceed to London and Copenhagen, thence to southern Sweden to visit their parents. They will then motor to Stockholm and across Sweden to Norway and back to Gothenburg, returning to America about Sept. 29.

Donald P. Hess has become general manager of the Columbus plant of the Timken Roller Bearing Co., succeeding C. N. Replogle, who has resigned. Hess has been connected with the Timken Roller Bearing Co. at its headquarters plant in Canton, Ohio, for nearly three years as assistant works manager, in direct charge of steel and bearing production. His connection with the automotive industry extends over a period of about ten years, during which time he served as chief of the priority section of the motor transport section in Washington during the war.

H. J. Thorkelson, M. E., formerly assistant superintendent of the J. I. Case Plow Works Co., Racine, Wis., but since 1914 business manager of the University of Wisconsin, Madison, has resigned to become associated with the General Education Board, New York City, to assist colleges and other educational institutions in problems of organization, budget and financial management. Mr. Thorkelson is a graduate of the College of Engineering, University of Wisconsin, 1901.

J. A. Flannery, a well-known automobile export man, has been appointed assistant export manager for the Haynes Automobile Co. of New York, according to an announcement by E. W. Headington, general manager of the New York Haynes company. Mr. Flannery has had wide experience in the export departments of leading American automobile companies, and is a specialist in the analysis of foreign markets, from the sales point of view.

A. W. L. Gilpin, for six years manager of the Milwaukee branch of the Ford Motor Co., has been promoted to district manager, was tendered a banquet at the Milwaukee Athletic Club by 208 Ford dealers of Wisconsin. Mr. Gilpin has transferred his headquarters to Chicago, as manager of the Middle Western branches and assembling plants.

F. E. Greene, who has years of experience in designing and manufacturing in art metal products, will have complete charge of the

production and distribution of the English & Mersick Co., which will commence the manufacture of a complete line of artistic interior mountings and fittings, including dome lamps, etc., at New Haven, Conn.

H. M. Sallabury, export manager for the Maxwell Motor Sales Corp., sailed Thursday, July 14, on the S.S. Mauretania for England, France and Holland, where he will spend some time in looking over the field with a view to determining what may be expected from that quarter in the coming year.

## INDUSTRIAL NOTES

Allith-Prouty Company, Danville, Ill., has purchased the plant and good will of the D. & G. Shock Absorber Company, manufacturing various kinds of motor vehicle accessories at Crawfordsville, Ind., and has removed the machinery and other supplies to the former's plant at Danville. The D. & G. company is one of the earliest in this field and has been doing a prosperous business for many years. S. E. Kerr, who has been superintendent of the Crawfordsville plant, will be retained by the Allith-Prouty company and possibly a number of the traveling salesmen. For the past six years the purchasing company has been furnishing the castings and various other parts for the absorber company, and it was decided that the overhead expense could be greatly lessened by the consolidation of interests, much of the present administrative cost to be eliminated by the amalgamation. "We hope to increase the production greatly," announced President H. C. Smith of the Allith-Prouty company. "We will make the shock absorber one of our leading lines."

The Moloch Co., Kaukauna, Wis., a consolidation of the Kaukauna Machine Works Co., manufacturer of power hammers and other tools, and the Moloch Automatic Stoker Co., has started operations in its new plant, erected at a cost of \$200,000. There are two buildings, each 100 x 250 ft., of brick and steel, consisting of a foundry and a machine and assembling shop. The manufacture of Mayer power hammers, used widely in automotive shops throughout the world, is being increased about 100 per cent, and several larger sizes are being added. The other major department builds automatic stoking devices for boiler houses of steam generating plants.

The A. H. Petersen Mfg. Co., 1614 Fratney Street, Milwaukee, for several years one of the largest exclusive manufacturers of tools and dies in the Middle West, is discontinuing this line and will concentrate on the manufacture of portable electric drills and similar equipment for automotive shops, garages, machine works, etc. The plant is being retooled and a regular production schedule will be resumed about Aug. 1 or 15 with 200 operatives.

Transport Truck Co. has completed arrangements with Keegan, Aprahamian & Co. of New York to take charge of transport business in Japan, China, the Philippines, Dutch East Indies, French Indo-China, Malay states, Straits Settlement, Burma, Ceylon, India, Persia, Egypt, Arabia, Siam, Australia, New Zealand, Tasmania and South Africa.

The Co-operative Axe & Tool Co., Chicago, operating plants in Chicago and Cleveland, Ohio, is establishing a third works in Green Bay, Wis., in an existing building, which is being equipped for electroplating and polishing. Later a steel refining plant and a drop forge shop will be added. E. D. Woods of Chicago is general manager.

The McAvoy Mfg. Co. of Racine, Wis., a pioneer manufacturer of winter tops for passenger cars, bodies, trimming, curtains, etc., has incorporated its business as the Wisconsin Top Co., Inc., with a capital stock of \$200,000. The incorporators are C. V. McAvoy, L. M. Johnston and A. M. Kalamattiano.

Republic Rubber Co. (C. H. Booth, receiver) resumed operations in the production of pneumatic tires, tubes and solid tires Monday, July 11, at Youngstown, Ohio. The mechanical goods manufacturing departments will resume Monday, July 18.

McCord Mfg. Co., Inc., reported July 12 that the company had placed its two plants at West Pullman, Chicago, on the market.

## Electric Service Men Discuss Rate System

NEW YORK, July 18—The relation between the car dealer and the electric service station was the principal topic of discussion at the meeting of the eastern section of the National Electric Service Association held here. H. R. Cobleigh of the National Automobile Chamber of Commerce brought out the importance of taking the owners' viewpoint and discussed briefly the advantages of the flat rate system in selling service.

J. H. Hearnan of Trenton, N. J., read a paper in which he emphasized the importance of securing the co-operation of car dealers in getting purchasers of cars to register the electric equipment on the car with the electrical service station. I. McCulla, service manager of the Bijur Motor Appliance Co., presented some ideas on inventory systems.

A dinner was held in the evening at which Harry Tipper, business manager of AUTOMOTIVE INDUSTRIES, spoke on "The Value of Organized Effort."

## STORAGE BATTERY MAN DIES

NEW YORK, July 18—The death is announced of Albert Taylor, manager of the North Atlantic district for the Electric Storage Battery Co. He passed away a few hours after becoming ill in his office in this city. His home was in New Rochelle. He was born in Liverpool, England, in 1864. Taylor joined the Electric Storage Battery Co. as a salesman in 1898 after having served with the Edison, General Electric, the United States Electric, the Westinghouse and Stanley Electric companies.

## PACKARD SALES ARE HEAVY

NEW YORK, July 18—The Packard Motor Car Co. of New York reports that for the six months ended June 30 it sold 563 passenger cars and 493 trucks in the New York territory. Net profits after all charges were \$182,000. July has shown a large increase in "twin six" sales.

# Calendar

## SHOWS

Sept. 5-10—Indianapolis, Automobile and Accessory Show in conjunction with Indiana State Fair, conducted by Indianapolis Automobile Trade Association, John B. Orman, Mgr.

Sept. 28 - Oct. 8—New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 8—New York, Automobile Salon, Hotel Commodore.

January—Chicago, Automobile Salon, Hotel Drake.

Jan. 7-13—New York, National Automobile Show, Madison Square Garden, Auspices of N.A.C.C.

Jan. 28-Feb. 2—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.

Sept. 9 to 17—Ottawa, Ont., Can.—Ottawa Motor Show.

## FOREIGN SHOWS

September—Buenos Aires, Argentina, Passenger Cars and Equipment, La Pabellon de las Rosas, Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery, Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Sept. 5, 1921—Constantinople, Traction trials under the direction of the Turkish Ministry of Agriculture.

Sept. 23-Oct. 2—Berlin, German National Automobile Show,

Auspices of German Automobile Mfg. Ass'n and German Automobile Club.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.

March, 1922—Santiago, Chili, Annual Automobile Show.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador, Automotive Section.

Sept. 1922—Rio de Janeiro, Brazil, Automobile exhibition in connection with the Brazilian Centenary Association Automobillista Brasileira.

## CONVENTIONS

Sept. 14-15-16—Portland, Ore., Credit Convention Motor and Accessory Manufacturers Association.

Oct. 12-14—Chicago, Twenty-eighth Annual Convention National Implement & Vehicle Ass'n.

Nov. 22—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

## RACES

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

## Start Dredging Hudson for New Ford Factory

TROY, N. Y., July 20—Work on dredging out the Hudson River at Green Island, near Troy, will be started this week, the first step in the erection of the new Ford Motor plant. A contract calling for four electric generators has been awarded to Allis-Chalmers Mfg. Co. Generator contract calls for the expenditure of approximately \$200,000.

Actual construction work on the building of the new power house has been started. The contract was secured by Stone & Webster, who will build the power plant on a Government dam erected some time ago and will have a capacity of 8,000 hp. As announced, Ford Motor Co. will build a tractor plant at Green Island but work on this has not yet been started.

Ford was one of the first to secure a license for erection of power plant under the terms of the Federal Water Power Bill. Permission was given by the Government last May.

## Culp Has Distributing Plan for the Tire Field

NEW YORK, July 20—A new plan of organization and distribution in the tire field is being presented by George K. Culp, Inc., this city, the head of which has been connected with the tire industry in various capacities for nine years.

The plan includes the association of a large number of rubber manufacturing companies and a large number of distributors on such a basis that all concerned will have a direct interest in the enterprise. Mr. Culp states that he is in communication with about 40 tire companies and has already practically consummated arrangements with the following:

Combination Rubber Mfg. Co., Bloomfield, N. J., to make Culp cord tires; Semple Rubber Co., Trenton, to make Culp red tubes; Chillicothe Tire and Rubber Co., Chillicothe, Ohio, for Ford size fabrics; Converse Rubber Shoe Co., Malden,

Mass.; A. J. Stevens Rubber Co. of Kansas City; C. Kenyon Co., Brooklyn.

The tire stores and distributors which have allied themselves with the proposition include: Bert A. Hosford Co., Denver; City Quick Tire Service Co., Tampa; Marathon Tire & Rubber Co., Milwaukee; H. S. Michael, Baltimore; Murray Tire Service Co., Kansas City; Pace Tire Co., Albany, Ga.; Easton Tire Co., Easton, Pa.

## Two Entries Drop Out of French Grand Prix

(By Cable to AUTOMOTIVE INDUSTRIES)

PARIS, July 20—The Talbot-Darracq and Sunbeam entries for the French Grand Prix which is scheduled for July 25 at Le Mans have been withdrawn because of dissatisfaction with the rules of the Automobile Club of France limiting the practice hours. The Fiat entries previously had been withdrawn on the ground that the race would not be representative of the best cars in Europe. As a consequence there is a possibility that the race may be abandoned.

## HAYNES ADDS NEW MODEL

KOKOMO, IND., July 19—The Haynes Automobile Co. has brought out a new model which will be known as the Haynes 75. The new car has a six-cylinder engine with cylinder dimensions of 3½ x 5 3/16 in., 132 in. wheelbase and 34 x 4½ in. tires. Prices are as follows: Roadster, \$2,685; 5-passenger touring, \$2,485; 7-passenger touring, \$2,485; Brougham, \$3,185; Sedan, \$3,485.

## FILE INCORPORATION PAPERS

STEVENS POINT, WIS., July 18—Articles of incorporation have been filed by the Hutter-Shutter Co., which is organized to manufacture a metal device designed for assisting in the heating and cooling of motor car and truck radiators. It is in the form of a shutter operated from the dash or by thermostatic device. The principals are A. D. Hutter, L. F. Hutter and H. M. Hutter.

## Suggest U. S. Hold Own Show in Great Britain

LONDON, July 1 (By Mail)—There is some outcry and protest against the refusal of the trade society—the S. M. M. and T.—to readjust the ballot process for allotting spaces at the trade show of cars. Last year's experience of the White City division of the show showed that Olympia had at least 30 per cent better attendance than the White City, and it was proposed that if the ballot for allotment were freed from the preferential or priority accorded to certain vested interests, it would reconcile the trade to a discrepancy which can only be remedied by a building big enough to house the whole show simultaneously.

The obvious course is for the importers of automobiles to frame their own show and run it as and when they like. Possibly Olympia will not be available to them, either because it is already booked up, or which is likely, the S. M. M. and T. have a restrictive bond with the owners.

## Tests of Tractor Plows in Italy Are Satisfactory

WASHINGTON, July 20—A trial giving satisfactory results was recently made at Sarissola, near Genoa, of tractor plows manufactured by the Ansaldo Co., in their plants at Sampierdarena, where they have now begun on a large scale the manufacture of agricultural machinery and implements, for which until lately Italy was entirely dependent upon foreign countries, states a report from American Consul General John Ball Osborne, Genoa.

The Ansaldo Co. has undertaken the manufacture of all the various types of plows, 40 in number, needed for the different kinds of Italian soil, which vary greatly according to the locality, so that it can now compete, both for quality of material used and accuracy of work and price, with all the foreign houses manufacturing special types of plows.

### *Concentration in Buying*

There are clear, logical, convincing reasons why it is to your advantage to purchase *all* of your automobile body hardware from one source. These reasons will come to your desk and appear in your trade magazines. Look for them. Read them. Digest them.

FOUR years ago—a small machine shop with few workmen and meager equipment—but with a definite policy of building a *quality* product—the Ternstedt Window Regulator.

Today—three giant, up-to-the-minute factory structures, totaling more than 200,000 square feet of working space, echoing to the daily hum of industry—in these buildings the finest of modern equipment, manned by 1500 conscientious *workers*, each a skilled craftsman on his particular job—the same policy of *quality* prevailing, only intensified.

Today, Ternstedt will supply you with *complete* hardware equipment for all closed body work, with many of the items required for open bodies as well.

This enables you to buy *all* of your automobile hardware from one source—to concentrate your purchases in one organization—freeing yourself from the worry, expense and loss of time attendant upon the purchasing of your hardware from a hundred and one different places.

The logic of the idea quickly appeals; to such an extent, in fact, that many companies already have lined up their entire requirements for future production with us.

May we tell you more about it?

NEW YORK—THURSDAY, JULY 28, 1921

No. 4

## 9,257,575 Cars and Trucks in Mid-year Registration Census

July figures show gain of 1,354,497 over year ago. New York leads, Ohio second; Maryland has largest percentage gain with 49.15. One car for every 11.4 persons in country. California goes ahead rapidly.

**A** GAIN of nearly a million and a half is recorded in automobile registrations for July 1, 1921, as compared with July 1, 1920. Despite the serious industrial depression which has swept the country, there is a substantial gain in registrations over the corresponding period of last year. The actual gain, excluding the Minnesota figures, is 1,354,497, an increase of 17.80 per cent. The present registration total is 9,257,575. There is one car for every 11.4 persons in the United States.

For the first time in several years New York has held its lead at the mid-year mark. It holds the premier place, however, with a total registration of 650,530. Ohio is second, with 623,316 cars and trucks within its boundaries, while Pennsylvania is third, with 609,268. Illinois occupies fourth place and makes its first entrance into the 600,000 class.

This figure cannot be taken as a definite statement of the number of automotive vehicles in use at the time the figures are dated. Rather is it a statement of the degree of law enforcement this year. It is a fact that in many agricultural communities the law officer in charge of the enforcement does not require the purchase of new licenses until after the crop money is received in the community. This fact, rather than large purchases, explains the heavy registration that always is reported in the last half of the year.

The fact that the mid-year registration shows an increase of 46,032 cars and trucks over the year end, a percentage gain of .52, is a distinct and clear refuta-

tion of the many prophets who declared that the automotive transportation was a luxury and that a distinct recession in the number of vehicles used would be noted with the need of greater economy in methods of living. There can be no question that many trucks have not been licensed this year—because there is not sufficient industrial activity to demand the available freight transportation—so that the gain must be in passenger vehicles.

### Substantial Gains Made

A study of the table of gains and losses from mid-year 1920 to mid-year 1921 indicates a healthy progress for the period. Five states failed to reach the previous total, as against one that was in the minus column last year. These five delinquents, however, are all predominantly agricultural states. In such states it is reasonable to believe that the law has not been strongly enforced up to this time, because of the peculiarly bad position of the average farmer.

This explanation of delinquency being accepted, the loss in Tennessee, South Dakota, Montana and Idaho seems certain to be turned into a substantial gain before the final count is made. The only decrease of importance is in Georgia. Even there, however, the decrease is only 13 per cent of the total of last mid-year. Since it is probable that the laxity in law enforcement is in proportion to the financial status of the farming population, even Georgia bids fair to do well during the remaining months of the year.

California records the largest gain over last July with 167,536, while New York, Texas, Illinois and Pennsylvania follow, each with a gain of more than 100,000. A substantial percentage gain has been made by the chief industrial states over last mid-year. Massachusetts has gone ahead nearly 29 per cent, Michigan about 24 per cent, New Jersey about 21 per cent, New York about 33 and Illinois and Pennsylvania about 20.

It is interesting to compare the gains made in these industrial states during the last year with those made last year over July 1, 1919. The list is as follows:

	July 1, 1920- July 1, 1921	July 1, 1919- July 1, 1920
Massachusetts . . .	28.91	11.04
Michigan . . . . .	23.81	28.66
New Jersey . . . .	21.59	34.88
Illinois . . . . .	20.75	23.90
Pennsylvania . . . .	20.39	24.06
New York . . . . .	33.79	11.29

These figures indicate that there has been no unusual falling off even in the rate of increase in these key industrial states. This same condition is present to a large extent in the case of nearly all the states.

#### District Figures Confused

Difficulty has always been experienced in obtaining District of Columbia registration figures. The method of compiling registrations there is apparently very much confused, with result that it is difficult to determine accurately at any given time just what the figures stand for. This confusion has made necessary a correction in the year-end figures for 1921, and on the basis of this correction the actual and percentage gains of the District have been computed. For that reason the present gain and loss figures of the District will not be compatible with the figure given

for total registration in our previous compilation.

Neither the actual nor percentage increase in registrations is given for Minnesota, nor have the Minnesota figures been considered in determining total gains. This is because there is no basis for satisfactory comparison with the past. The total registrations for Minnesota given in the large table constitute the first figures for that State of any real value in determining the number of cars actually in use.

Previous to January 1, 1921, Minnesota had a triennial registration system in which the registrations were cumulative for three years. Thus it was impossible at any given time to determine even approximately the number of cars actually in use. The last legislature changed that system, however, and Minnesota is now on an annual registration basis. No

\*Estimated.

single factor has been responsible for so great differences in various registration compilations as the Minnesota figures. It is good to know that this one difficulty, at least, has been eliminated.

Even the present figures are probably none too accurate as indicating the number of cars now in use in Minnesota, however, since the legislature made no provision for registration until just before its adjournment, and officials are having some difficulty in getting the new system into efficient operation. Our correspondent states that "hundreds of cars are still carrying 1920 numbers."

The figures indicate anew the necessity for uniform methods of car and truck registration. The increased

prominence of territorial analysis in merchandising has rendered accurate registration statistics of even greater importance to the industry than ever before. Such statistics can never be obtained while the present confusion of State laws and methods remains.

The difficulty lies not so much in the deficiencies of particular State laws as in the lack of uniformity of practice, which makes it impossible to accurately correlate the figures of the various states. It is true, however, that the actual practice in many states is loose, inaccurate and confused.

As long as this is the case it will be necessary to compile and interpret registration statistics with extreme care. Gross errors can be made by a superficial acceptance of figures obtained from State officials, or even from published compilations, unless the factors of variation and error are understood.

Mid-year figures, in particular,

should be accepted for what they are—an indication of the trend for the year. It is not always possible to get the totals as of July 1 exactly, and it is obvious that one day or week in variation in the date at which the figures were given would mean considerable difference in the totals.

### Basis of Comparison

It is possible to compare only like units, if the results obtained are to be fair. The July 1, 1921, figures, for example, can properly be compared in every way with those of July 1, 1920. It is fair to judge the present status on the basis of the status at the same time last year, and it is in this way that the chief comparisons in this article are made.

Mid-year and year-end figures are not commensurate. The enforcement of the law varies greatly, for in-

stance, in the different states, and a State may appear below normal in July simply because no attempt has been made to enforce the law until late in the year. Especially is this true of agricultural states and communities where the sheriffs frequently make no attempt to collect license fees until crops are harvested.

The past record of New York illustrates this point clearly. Every year, recently, New York has been behind Ohio on the basis of July 1 figures, but always shows a proportionately large gain during the last six months and passes Ohio in the final tabulation by many thousands.

Thus the failure of a State to attain last year's total by July 1 is of little significance. Where a State has passed the final figure of 1920,

however, some importance may be attached to the fact, since a gain for the year is already assured.

**Comparison of Year-End and Mid-Year Figures**

It is with this thought clearly in mind that an examination of these mid-year figures, as compared with the year-end figures for 1920, should be made.

The mid-year total is 46,032 in excess of the high point reached last December. This is a gain of .52 per cent and insures a 1921 gain in automobile registrations. The previous discussion of delayed law enforcement applies with equal force in making this mid-year and year-end comparison.

While 27 states have thus far failed to reach their year-end total, the 21 which did surpass their previous record more than overcame the losses. The big industrial states, which may be said to reflect the business trend of the country, practically

all show substantial gains. The four leaders in this respect, for instance, are Pennsylvania, Illinois, Michigan and Wisconsin. This is a decidedly encouraging sign. New York's drop is simply consistent with its normal course every year, as previously explained, while the Massachusetts decrease is only 1.5 per cent.

The largest decrease, both in actual numbers and in percentage, is shown by Georgia. This State has 25,770 less registrations than on January 1, 1921, a decrease of 17.80 per cent. Seven states showed a decrease of more than 10,000, while nine states gained more than 10,000.

Comparison of mid-year motorcycle figures is not possible in all cases, because midyear figures were not available last year from every state.

# Handling Light Railway Passenger Traffic With Motor Trucks

How some short line roads have met prohibitive operating costs of steam equipment by the use of motor trucks fitted with steel wheels to run on rails. Details of mechanical arrangement, operating cost, etc., are given.

By Donald A. Hampson

IN the western part of New York State there is a 57-mile railroad running north and south through an old settled region typical of the East. Not lying in the direction of the country's commerce, there is no through business, but connections are made with trunk lines at each terminus; the villages along the line total 6500 inhabitants, besides which there is the customary rural population found in every farming and woodland region. This road was built more than 50 years ago and enjoyed the usual career of so many short lines, going from bad to worse, until in 1917 the owners gave up operation rather than face the ever-mounting costs.

This was a hard blow to the region—the full value of any service is never so keenly realized until after it is gone. In 1920 a group of local business men bought the road and put the two 50-ton locomotives and the track in shape for freight service. The volume of latent business in the territory is reflected in this service as it exists to-day; a train is run up one day and back the next—its average load is 22 cars per trip.

But the seven passenger stations have not been opened. A train that consumes nearly a day in making 57 miles cannot offer even "mixed" service (the crew does the switching at more than twenty sidings on the way). The management has not the capital to buy a locomotive and coaches for the traffic, and the remains of former equipment were too dilapidated to think of patching up—moreover, while they know the traffic is there, the returns from passenger business, even at present high rates, are not sufficient to warrant the expenditure, and the business would have to be carried on at a loss, just as it was formerly. An idea of what business lies dormant, the receipts from the passenger train in 1917 are quoted as passengers, \$15,506; mail, \$3,309; express, \$1,622; excess baggage, \$155; making total gross receipts of nearly \$21,000—present rates would increase this one-third, but even that is ridiculously small, compared to the cost of adequate steam service.

The above is a good example of the railroads that adopt service by gasoline-propelled vehicles. The population is there, they have the money to ride, the roadbed is there—all that is lacking is a low-priced, self-propelled car. Such a population does not ask for Pullman service or excessive speed—what they want is to be able to get back and forth once or twice a day for shopping and business purposes.

Two gasoline cars on this line could make a round trip each day, affording speedy, comfortable service the year around at such a cost that if there were only three passengers per trip, they would pay the expenses, including amortization in three years. There are but fifteen miles of improved highway parallel to the railroad mentioned, and for six or seven months in the year the only way to

reach the several communities is by wagon or sleigh. One-man cars geared for 20 miles per hour would make good time and negotiate the grades on high—the driver would collect cash fares, doing away with ticket and agent expense.

The photograph, Fig. 1, shows a car for this class of service. It is a stock speed wagon truck with standardized body and railroad equipment. Its leading dimensions follow:

Engine—4 cyl., 4½ x 4½ in.  
Maximum engine speed—1700 r.p.m.  
Transmission—3 speeds forward and 1 reverse.  
Gear ratio—3.73 on high, 14.5 on low.  
Car speed—42 m.p.h. maximum.  
Chassis—Reo 1¼-ton.  
Weight empty—5400 lb.  
Rear axle—Full floating.  
Track gage—56½ in.  
Driving wheels—30 in.  
Truck wheels—20 in.  
Fixed wheelbase—128 in.  
Total wheelbase—144 in.  
Seating capacity—19 plus the driver.  
Body length—146 in. outside posts.  
Body width inside—84 in.  
Body height, center—78 in.  
Seats—Heywood Wakefield, rattan cushions and backs.  
Starting and lighting—Electric.  
Price—\$4,500, approximately.

For the purposes of the railroad to which it was delivered—a 15-mile steam line through a fairly level

country—this car is geared to run 40 m.p.h. at a little under maximum engine speed. A time card of this run is given; it shows that the car works in conjunction with the steam mixed train, but that the car has several flag stops to make—its schedule is faster than the train's.

From the train record sheets, it is shown that this car ran 2577 miles in the first month of its operation with a consumption of 266 gal. of gasoline and 19 gal. of oil. The first few days of operation the gasoline consumption was high, but as the mechanism "found itself" the curve dropped enough to show an average mileage of 10 per gal. for the whole month. The following months the average mileage was higher. A 31-passenger car of similar construction on the same road geared to run a maximum of 30 m.p.h. has shown practically the same mileage.

Taking these figures, we may arrange a chart of operating expenses as shown below. Explaining the items, the driver's pay is figured at 60 cents an hour, a helper at 40 cents an hour, four hours a day to clean the car and assist in filling tanks, etc., and the chief item of repairs includes a proportionate mileage charge for replacing a master gear and pinion installed near the 6000th mile when a thrust collar loosened up and chipped off a tooth.

Gasoline .....	\$79.80
Oil and waste .....	21.00
Insurance .....	25.00
Driver .....	162.00
Helper .....	43.25
Repairs .....	20.00
Depreciation .....	125.00
	<hr/>
	\$476.05

Dividing this by the mileage, 2577, we find the investment and operating charge amounts to 18½ cents a mile. The railroad is permitted to charge a passenger rate of 5 cents per mile. Without a doubt, no other type of rolling stock would show as well under a similar analysis.

### Features of the Body

The body is designed to provide maximum seating capacity in minimum length, the primary object being to avoid overhang at the rear. Overhang is objectionable because of the swing on curves, especially in yards, and it puts a greater load on the rear axle. The body follows somewhat that of "safety" street cars in offering maximum capacity with simple operation and light weight, though the construction is much heavier than

Fig. 1—A Reo Speed Wagon with special body, fitted for operation on rails

ordinary bus jobs. One feature of construction follows a truck design described in *AUTOMOTIVE INDUSTRIES*, Aug. 12, 1920, in that there are no longitudinal center sills—the chassis frame answering for these—the cross sills, 2 x 3-in. ash, rest on and are bolted to the frame, with their ends leaded and mortised to the side sills. Not only is weight saved but the body is that much lower.

Fig. 2 is a floor plan and shows the seating arrangement. There is a safety door at the rear, normally blocked by a seat cushion, and an entrance at the right of the driver with a leaf door operated by him. Hand holds are provided inside and out. The inside finish is natural wood, matching the rattan seats and presenting a bright, clean appearance. The seats are full size and comfortable, spaced according to street car practice, and the general riding effect is equal to or better than that of street cars and far better than highway buses.

The seating arrangement insures maximum traction with any load; cross seats are always preferred to longitudinal ones and these, directly over the driving wheels, always fill up first. Designed for 19 passengers, this car is often grossly overloaded, records of the afternoon trip showing as high as 33 carried. It is customary to estimate passenger loads at 160 lb. per person—this rating makes the ratio (full load) of paying load to dead weight 3040 to 5400—a most unique record in railroading!

Two points in body construction are different from bus body practice—they may be noted in the photo. Windows set a few inches higher become a safety feature because they guard against hands and arms thrust out of them. Bodies ordinarily have swinging front windows which may be adjusted and held by a fastening—this construction is frail and develops a bad case of rattling after a few weeks' service. In this car the windshield is left in place and the body built to surround it; by so doing, first class steel and glass construction, permanent and quiet, takes the place of ramshackle parts.

### Railroad Equipment

Some of the features applied particularly for railroad service may be noted by reference to the photograph. These are the electric marker lights, front and rear, electric headlight, sand boxes and brakes. The wheels conform to Master Car Builders' shape and have hard faces. A lever at the driver's right, under his seat, operates the gates in the sand boxes, which are of the hopper bottom type and located inside the car under the seats where it is dry. An exhaust whistle is used for signals. At the rear of the car is an M.C.B. automatic coupler. This is attached without draft gear, which has been found unnecessary for starting one trailer.

Fig. 2—Plan and Fig. 3, side elevation of body layout employed

The car is ball and roller bearing throughout. It offers a resistance of 15 lb. per ton in starting, dropping off to 10 lb. at 4 m.p.h. One man can easily push the car on a level tangent. It has a theoretical tractive effort of high gear of 182 lb. and has shown its actual pulling ability by hauling the larger car as a trailer (weighing 9000 lb.) and making its time card schedule.

Brakes are provided all around. They make for rapid deceleration and consequent improved running time. A pedal operates the band brake on the rear wheel drums just as in automobile practice. The front truck has regulation brake shoes carried on I-beams, inside hung.

The method of hooking up the front truck brakes is novel and proved successful from the start. Fig. 4 shows the scheme. It was evolved to allow the front truck the greatest swivel movement ever necessary, to avoid the use of cables or chains or radius bars, and yet to have the brakes always in position to be applied with the same amount of hand wheel movement, this to be the least possible consistent with brake shoes free from drag. The otherwise useless steering wheel is used for a hand brake wheel, as in all front truck braking systems. A ratchet and pawl are unnecessary with such a brake on a gasoline car as holding the pressure for the few seconds at a time required imposes no hardship on the driver.

Referring to Fig. 4, power applied to the 18-in. wheel is transmitted through arm and drag link to a ball joint at the end of the lever H, which engages the square head of the truck king bolt J at whose lower end is keyed the cam K, which spreads the brake beams. A turnbuckle (not shown) in the drag link and the substitution of a sector D, which is nearly half a circle in extent, permit adjustments for wear and position. It is evident that as the truck swivels the brake beams turn the cam between them—there is no backlash to take up and this turning merely rotates the steering wheel. The greatest movement of the latter is that necessary to take up the running clearances and the spring in the parts—track layout has nothing to do with it. The front truck has a swivel center bearing and it has a tubular center "pin" surrounding the king bolt and relieving the latter from binding.

#### Applying Railroad Equipment

Disregarding the matter of bodies, the process of applying these standardized railroad members is very simple. The easiest way when possible is to do the work where there is a pavement flush with the rails. If not this, the car is run on a crossing or planks are laid ad-

Fig. 5—Narrow gage car designed for use on a South American railroad

acent to a crossing or a spot selected with earth the full height of the rails. The chassis is run to the selected spot on the rubber tires and placed directly over the rails. Jacking up the rear end, the wood wheels are disassembled from the hubs and the metal ones put in place, using the same bolts. Then the front end is jacked up and the axle with wheels intact removed; the front truck, already on the rails, is run back, the car lowered and the spring clips attached to the body bolster. Not even an extra cotter pin is needed. With the engineering work properly done, the change can be made in three hours and the erstwhile motor truck becomes a railway car—such are the essentials, other equipment is a matter of selection.

#### Narrow Gage Roads

Heretofore, we have considered only equipment for the U. S. standard gage of 56½ in. Fig. 5 illustrates a narrow gage car that has been running in South America for about a year. Its run is over the line of a 42-in. gage steam road with a first class roadbed about 150 miles in length. Part of the line is situated on the high plateau at an elevation of 3½ miles, then it descends to the lowland country, where it is intensely hot and moist. As is usual with these Andes railroads, the curves are sharp and the grades are steep; to successfully cope with these, a swivel front truck is applied, powerful brakes all around, 30-in. drivers are used, and the gear ratio made 4.7 to 1 on high.

So great an elevation and temperature range is a severe test of engine operation. Trouble in this respect was foreseen and the original layout included additional cooling capacity for the hot region and protection for the radiator and circulating water when traveling in the section of rarified air—these units to be controlled by handles placed within the driver's reach. However, it was finally decided to try the car without these and up to the present time, the dash carburetor adjustment has taken care of thermal conditions fairly well.

Altering the rear end for 42-in. track forced the removal of the brake drums. In their stead brake shoes and a brake beam were installed. Both here and on the front truck, extra leverage is provided to serve on the numerous steep descents. The truck brakes are of the design shown by Fig. 4; a leverage of 95 to 1 is provided. Brake shoes and holders are standard M.C.B. pattern and interchangeable with like parts on the road's steam equipment.

The chassis is the same as that of Fig. 1. The photograph shows the car about to be boxed for export. It shows also the sand boxes with operating connection terminating in a lever convenient to the driver's hand; a spring catch holds this lever so the pipe opening is

Fig. 4—Sketch showing method of applying brakes to wheels of the truck

Fig. 6—Diagram showing effect of centrifugal force in rounding curves

normally closed. The body is one of the familiar bus bodies seating 15 passengers on longitudinal leather-covered seats. The seat cushions are tilted to the rear and extra padding put in cushions and back to make more comfortable riding over long distances. Provision is made for exhaust heating.

### The Matter of Stability

In analyzing the various conditions and possibilities in connection with operation on the narrow gage railroad mentioned above, the question of overturning was considered. This has frequently been raised in connection with safe operation of motor passenger cars at high speed.

Refer to Fig. 6. The various units that go to make up

the weight were separated and their center of gravity determined; from these the center of gravity of the whole was found to be located at a point 33 in. above the rail. This is 21 in. below the maximum allowable height for safety on a 42-in. gage of track. The triangle O A B in Fig. 6 outlines the case. The total weight of car and load is 7500 lb.—it may be resolved into components bearing on each rail head.

The forces tending to overturn the car or cause it to mount the rail are (1) centrifugal force in rounding a curve, (2) wind pressure against side of car, (3) sway of the body. Consider the last first as it is least important; it is the lurch or swing of the body about spring joints as the leaves bend—a 72-in. wide body on springs spaced 36 in. with properly selected springs has negligible power to create serious sway.

Centrifugal force is figured directly from the car speed and degree of curve and car weight by the equation

$$F = 0.00001167 V^2 D W$$

which for the 7500-lb. car entering a 10 deg. curve at 30 m.p.h. is only 787 lb. Assuming this to act at the center of gravity and tending to overturn the car at either the point A or B, its moment is  $787 \times 33 = 25,791$ -in.-lb. This must lift the weight concentrated at the center which reduces its effect at that point by dividing by half the track gage, giving 1238 lb. that is resisted by a weight of 7500 lb. A factor of safety of 6 is thus revealed.

Wind pressure at 35 miles an hour would exert an effect equal to that of the centrifugal force, though slightly higher up. The combined stresses are even then well on the side of safety—rational operation would never place a car in position to receive the extreme conditions named.

(Left) Interior of motor-passenger car, showing seating arrangements for thirty passengers and two operators. This car was made by building a passenger car body on a three-ton F.W.D. motor truck and has been installed on the run of 50 miles between Algiers, La., and Buras, La., by the New Orleans and Lower Coast Railroad. (Right) Three-ton, Four-wheel-drive truck converted into passenger car and installed on the New Orleans and Lower Coast Railroad, near New Orleans, to replace entire passenger train of locomotive and five cars, formerly operated over a fifty-mile run between Algiers and Buras, La.

## Automotive Interest in Chemical Exposition

AT the urgent requests of numerous automotive engineers and manufacturers, motor boat and airplane builders, special attention will be given to the requirements of the automotive industry in the Seventh National Exposition of Chemical Industries during the week of Sept. 12, in the Eighth Coast Artillery Armory, Jerome Avenue and Kingsbridge Road, New York City. The setting for the chemical display this year will be in the building that housed the last N. A. C. C. motor truck show. The display promises to be the largest ever held.

Dyes are, of course, of interest to the automotive industry, since the enduring qualities of body and upholstery coloring mean so much to the looks of a car after it is some months old. Enamels, paints and processes will

be illustrated at the exposition and illustrated lectures on these subjects will be given by experts. Members of the Society of Automotive Engineers will be invited to attend these sessions.

Fuel and substitutes for gasoline are of interest to automotive men, and the lectures and demonstrations that will be part of the exposition will tell of the progress made in these lines. Recent discoveries in the manufacture and use of low test fuel will be of value to engineers, likewise many new metals and alloys will be on view. Studies made in aviation materials—the treatment of woods, fabrics, etc.—will be exhibited.

There will be more than 450 exhibits in the exposition and these will cover five city blocks of space.

# Highway Research Board Outlines Its Program

Selection of Prof. W. K. Hatt as director marks beginning of definite steps toward carrying out of work outlined at the conference in New York last November. Influence of the highways on design one problem.

**T**HE Advisory Board on Highway Research of the National Research Council announces that it has engaged as director, William Kendrick Hatt, Professor of Civil Engineering and Director of Materials Testing Laboratory of Purdue University. He is a member of the American Society of Civil Engineers, the American Society for Testing Materials, the American Railway Engineering Association and other technical societies. His work as an investigator in organizing the timber investigations of the United States Forest Service and in other engineering and scientific fields for the past twenty years is well known. His office is in the building of the National Research Council, 1701 Massachusetts Avenue, Washington.

This Advisory Board was established by the Division of Engineering of National Research Council, with the co-operation of Engineering Foundation, as the result of a conference held in New York, Engineering Societies' Building, last November, attended by many representatives of national engineering societies, associations of vehicle and road materials' manufacturers, Federal Bureau of Public Roads, State highway departments and universities.

By the terms of the by-laws, the membership of the Advisory Board is composed of those organizations of national importance interested in design, construction, economics, maintenance and financing of highways, in materials and equipment therefor, and in vehicles used on highways; governmental departments and bureaus of similar interests, and higher educational institutions. The present organization members are:

American Association of State Highway Officials.  
American Concrete Institute.  
American Institute of Consulting Engineers.  
American Society of Civil Engineers.  
American Society of Mechanical Engineers.  
American Society for Municipal Improvements.  
American Society for Testing Materials.  
Association of American State Geologists.  
Bureau of Public Roads, U. S. Department of Agriculture.  
Corps of Engineers, U. S. Army.  
Engineering Foundation.  
Federal Highway Council.  
National Automobile Chamber of Commerce.  
National Highway Traffic Association.  
Society of Automotive Engineers.

The officers of the board are: Anson Marston, chairman, director, American Society of Civil Engineers, member of Iowa State Highway Commission, and Dean of Engineering, Iowa State College; Alfred D. Flinn, vice-chairman, secretary, Engineering Foundation, and vice-chairman, Division of Engineering, National Research Council. Other members of the Executive Committee are Thomas H. MacDonald, chief, Bureau of Public Roads, Department of Agriculture; George S. Webster, president, American Society of Civil Engineers, consulting

engineer, formerly director, Department of Wharves, Docks and Ferries, Philadelphia; Henry M. Crane, chairman, Research Committee, Society of Automotive Engineers; W. K. Hatt, director.

In addition to the member organizations, thirteen State highway departments and more than forty universities have definitely signified their interest in the work of the Advisory Board and their willingness to co-operate.

The purposes of the board are:

- a. To assist existing organizations in outlining a comprehensive national program of highway research and co-ordinating their activities thereunder;
- b. To organize committees for specific problems;
- c. To act in a general advisory capacity;
- d. To serve as a clearing house for highway research information.

Three technical committees have been at work for a number of months. These are:

1. Committee on Economic Theory of Highway Improvement, Chairman, Professor T. R. Agg, Iowa State College.
2. Committee on Character and Use of Road Materials, Chairman, H. S. Mattimore, Engineer of Tests, Pennsylvania State Highway Department.
3. Committee on Structural Design of Roads, Chairman, A. T. Goldbeck, Engineer of Tests, Bureau of Public Roads, Department of Agriculture.

The Executive Committee of the Advisory Board has the creation of additional committees under advisement, such as committees on Vehicle Design as Related to a Road, on Economics and Cost of Transport, on Financing Highway Improvements, on Traffic Studies, and on Organization of Construction Plants.

Much valuable experimental research work is being done by the Bureau of Public Roads, the United States Army, several State highway departments, the universities and a few associations of manufacturers of vehicles and materials.

Two of the most important elements of the strength of the Advisory Board are the membership and the active participation of the Bureau of Public Roads and the army engineers. The bureau is represented by its chief, Thomas H. MacDonald, who is supporting the research work most loyally and intelligently. To represent the Engineer Corps of the Army, the chief of engineers appointed Colonel E. Eveleth Winslow, stationed at New York, and the appointment was officially confirmed by the Secretary of War. Major Mark L. Ireland of the Quartermaster's Corps is a member of the Committee on Economic Theory of Highway Improvement. During the summer, with the co-operation of the Massachusetts Institute of Technology, Major Ireland will conduct at Cambridge, Mass., an important series of tests on the traction resistance of vehicles and of road surfaces. Equipment and supplies have been provided and the necessary assistants assigned by the Army.

Director Hatt's work is expected to stimulate experimental work by such organizations to much greater activity, just as the work of the existing committees of the board has already had a stimulating effect. The director, in consultation with the Advisory Board, will prepare a comprehensive plan of the field of highway research, including economics, design, construction and administration, and will arrange a program of committee work for those fields that need to be occupied immediately.

The personnel of these committees will include active research workers within the State highway commissions, the universities, the governmental departments and other research organizations. A census will be taken of the research work completed and current, and the various research agencies will be invited to co-operate in an attack on those urgent problems upon the solution of which the future success of highway transport depends.

The Advisory Board will not duplicate the efforts of existing research groups. Indeed, it will not do any research work directly, but will act rather to promote a co-ordinated effort in a consistent national program, suggesting problems to those organizations best fitted to attack them. It will also serve as a clearing house for information.

As one highway commissioner has expressed the present need: "I have \$10,000,000 to spend on roads in my State this year. I know that I could save \$500,000 by properly directed research studies. If your board will

tell me what other states are finding out and what research work I should do to supplement their efforts, I will supply all the necessary men and funds." When it is considered that the funds available for the road construction program alone in the United States represent the expenditure of \$1,000,000,000, the cost of the overhead organization, such as that of the National Research Council, to unify research, is insignificant. There is abundant money available for the research itself. The Advisory Board on Highway Research of the National Research Council is in a position to co-ordinate such expenditures in a comprehensive national program.

An informational service, giving the results of current studies and advances in the art, will be supplied to various co-operating bodies at frequent intervals.

The program for highway research will not be limited to problems concerned with the construction and maintenance of roads from the ordinary engineering standpoint. It will also consider those important problems of economics of transport upon highways in relation to other transport agencies, the relation of the design of vehicles to the character of road construction, and the important problems of administration involving traffic regulation, fees and maintenance.

This is the first effort seriously to attack the whole problem of highway transport. With the earnest desire of all interested to co-operate, the efforts of the National Research Council, seconded by Engineering Foundation and national engineering societies, should be effective.

## A Steering Gear for Passenger Cars

A PASSENGER car steering gear of similar design to models produced heretofore for truck applications only is now announced by a well-known parts maker. In the new design the connection between the steering tube and the nut is a four-jaw connection without brazing. The screw threads are turned on one end of a forging, on the other end of which there is a rectangular opening. In this opening a rectangular piece of steel is inserted, which projects far enough on either side of the screw to engage rectangular openings in two swivels, one of which operates on either side of the screw forging. The rectangular openings in the swivels are long enough to permit the swivels to move transversely with the center line of the steering column. These swivels operate in two circular openings which are machined in two fingers projecting from the trunnion shaft. The distance between the center line of the openings in the fingers and the center line of the trunnion shaft is  $1\frac{5}{16}$  in. The resulting action when the nut is turned by turning the

steering wheel is that the screw moves up or down with the rotation of the nut. In so doing it carries along the rectangular block, which in turn carries the swivels, and rotates the trunnion shaft. The rotation of the trunnion shaft moves the steering arm forward or backward.

The advantages of this type of steering gear lies in the large bearing surfaces between the various operating parts. Large bearing surfaces tend toward safety, reliability and easy steering, as well as toward a reduction of wear on the threads. The new design is 2 in. wide at its lower part and the upper part of the housing, which also contains the ball thrust bearings, is only  $2\frac{1}{2}$  in. in outside diameter. This narrowness facilitates installation of the gear in passenger cars.

Ball thrust bearings are provided to take the end thrust of the nut in both directions. The trunnion shaft is  $1\frac{1}{4}$  in. in diameter and the steering arm is secured to the trunnion shaft by means of six taper splines. The steering gear is manufactured by the Ross Gear and Tool Co.

Ross steering gear for passenger cars

ACCORDING to W. T. Bonner, where both sets of brakes act on the same brake drum, it is a much better plan to secure the friction lining to the brake drum than to the brake bands, as is now the common practice. The heat generated by the friction of the brake no doubt is carried off quicker if the lining is on the drum, as it does not have to pass through the lining. It is claimed that the wear of the friction lining is more uniform and the lining wears much longer. Only one set of rivets are required for securing both the inner and outer linings. One objection would seem to be that since the service brake is used practically all the time, its friction lining will wear out much sooner than that of the emergency brake, and if both linings are secured by a single set of rivets, renewal of one lining alone involves difficulties.

# Effect on Fuel Economy of Refinements in Engine Design

Views of a British engineer specializing in carburetion, in regard to numerous factors of design which affect performance and economy. Pulsating flow, valve timing, scavenging, manifold design, combustion chamber shape and carbureter characteristics among items considered.

By L. Mantell\*

**T**HE factors which determine fuel economy in so far as they are at present understood in England, can be grouped under three general heads:

(1) The production of a well-disintegrated spray intimately mixed with air, a mixture not in constant proportions but varying as regards its air-gasoline ratio, according to the characteristic of the engine;

(2) The reduction to a minimum of all depositing agencies which may act upon the spray in its passage from the carbureter to the engine; and

(3) A design of combustion head and implacement of valves which will permit the highest possible charge turbulence, and maintain, by correct distribution of heat, the utmost uniformity of temperature throughout the mass of burning charge.

Were the current of air through the carbureter of a perfectly steady nature, such as would be produced by a rotary blower and the flow of charge in all parts of the induction pipe absolutely uni-directional it is probable that carbureter adjustment would be mathematically determinable; but the current is, of course, far from regular and by no means uni-directional, hence the wide discrepancies shown by comparing the carbureter adjustments and thermal efficiencies of different engines of the same capacity.

## Current Pulsations

Consider first the question of current pulsations. These are produced by exhaust back pressure, inlet back pressure, and by some other cause which is at present a little obscure, but appears to come either from the shock imparted to the moving current of gas by the closing inlet valve, or by certain shapes and areas of the induction manifold which intensify vibrations.

The predisposing causes of exhaust back pressure will be evident if we consider the progress of the exhaust stroke in the case of an ordinary touring engine with a muffler fitted. If the latter is very well designed with a view to the avoidance of back pressure and placed well to the rear where the exhaust velocity has decreased to a minimum owing to the contractive effects of cooling, its obstructive tendencies may be negligible, and at exhaust top center the residual pressure in the combustion head may be almost at atmosphere. But in the great majority of cases an engine so fitted will have a certain degree of positive pressure in the head at top center and therefore if the valve is closed at this point and the inlet opened very shortly after, it is most probable that a slight shock of back pressure will be communicated to

the entering column of charge before the action of the piston corrects its direction. Apart from this there will be in such circumstances an increased ratio of carbon dioxide present to vitiate the incoming gas and thus retard the rate of combustion. For this reason, among others, it is common practice in England to close the valve a few degrees late, generally about 10 or 12 deg.

Certain designers, however, favor the top center position for the reason that the small proportion of carbon dioxide present has the effect of softening the shock of the combustion, and imparting in this way an increased smoothness to the running of the engine. In the opinion of the writer this is fallacious practice, for the reason that an engine so timed must be very well designed as regards the shape of the combustion head and the size and disposition of the valves, otherwise, even with a thoroughly open and free exhaust system a slight vibratory blow-back is almost sure to set in.

It is found that engines timed in this manner invariably require unduly small choke areas in order to obtain good consumption, the reason apparently being that without an increased induction depression to damp out the tendency to blow-back this symptom develops to the detriment of a requisitely fine degree of spray suspension. It must be remembered that a pulsating series of gas-shocks has the effect of coalescing the finer particles of fuel into coarser globules which enter the combustion head insufficiently mixed with oxygen to burn at a useful speed, and are therefore ejected at the exhaust in a cracked or partially burned state, where their presence can be detected and measured by analysis of the exhaust gases.

Apart from this, an engine originally timed to close its exhausts on top center will do so before top center after a certain amount of cam wear and tappet side play has set in. Also, there is no margin left for such exigencies as a dirty silencer, or late or weak ignition. It seems, therefore, much sounder practice to close this valve at an appreciable distance over the top center.

The object in giving the inlet valve a closing lag is to cope with the wire drawing to which the induction current is subjected, and thus permit time for a more complete charge to enter the cylinder. If the valve is held open beyond the point where the minus pressure in the cylinder, which obtains during the induction stroke rises to normal, the action of the ascending piston will surely impart a series of shocks to the incoming current.

It might appear that the retarding effects of the throttle when running at a moderate pace and load would obviate any chance of a shock being imparted to the current in this way. It seems, however, to be the case

\*The author is connected with the Solex Carbureter Co.

Fig. 1—Example of two-port T pattern exhaust manifold. Fig. 2—A well-designed four-port exhaust manifold. Fig. 3—A slightly defective Y pipe. Note the direction part of each discharge tends to take in its passage to the main pipe. Fig. 4—Unidirectional flow pipe for four-cylinder engine using two carbureters. Fig. 5—Unidirectional flow pipe for six-cylinder engine with two carbureters. Fig. 6—Straight induction pipe with carbureter at each end. Fig. 7—Side and end views of induction pipe with carbureters opposite ports 3 and 4.

that an unduly late inlet closing point, although in many instances it undoubtedly increases power at high speed, has a bad effect on consumption when running at low throttle positions.

The prevailing tendency among English designers is to close this valve rather too late, and the writer has seen many instances in which considerable improvement in economy has been effected by regrinding the cam so as to give less closing lag. It must be admitted, however, that cases are occasionally noted when quite good economy is obtained with timings that in an average engine would certainly cause waste.

From about 40 to 45 deg. late seems to be a favorite position for closing the inlet in English cars, but the writer has seen many cases in which this lag has been reduced to half that amount without appreciably impairing the power and with a considerable increase in economy. In slow speed truck engines particularly is this true.

There is more than one engine on the British market, which, in other respects well designed, is spoiled by an undue inlet closing lag. The simplest remedy, which is only in the nature of a compromise, is to use a small choke, or as the case may be—a heavy spring or gravity valve, where a carbureter of the constant vacuum type is employed.

#### Inertia Factors

If the exhaust valve still remains open too late the column of moving gas in the exhaust tract sometimes causes a minus pressure in the clearance space. Advantage may be taken of this by opening the inlet valve at the point where the minus pressure sets in and thus permit the head to be flushed and scavenged, while the piston is, comparatively speaking, at rest. An overlap of this nature occasions waste owing to the charge from the inlet tract escaping via the exhaust when the overlap is carried to excess, but a limited amount of overlap is economically advantageous.

Since the velocity of the exhaust column affects greatly the completeness of the scavenging, it would appear that the position of the opening point of each exhaust

valve in a four-cylinder engine must control to an appreciable extent the value of the auto-scavenging vacuum of the previous cylinder in order of firing. A careful study of the variations in carbureter adjustments called for by alterations in the opening points of the exhaust would appear to show that the fixing of this point is very potent, not upon its own cylinder, but evidently upon the preceding one.

#### Exhaust Manifold Design

The manifold has a considerable effect upon pulsations, and the design and shape of the exhaust passages and manifold are important.

While most engine makers are fully aware of the necessity for providing the utmost freedom and constancy of direction where high efficiency engines are concerned, it would seem from the frequency with which errors occur in the design of these parts that many British manufacturers are under a considerable misapprehension as to the extent to which this rule applies in the case of ordinary touring car engines.

While, for instance it is neither necessary nor desirable that a touring engine should be fitted with a long and open main pipe into which the port leads are very gradually swept by wide bends, it is, on the other hand, going to be quite the opposite extreme to cast the manifold integral with the cylinder block, and add to that offence by placing it in such a manner in relation to the valve pockets that the gases on emerging therefrom are bent sharply at a right angle.

The effects, of course, are two-fold: An incurably pulsating current owing to exhaust obstruction and, in many cases, overheating.

Few engines are now designed with cast-in exhaust manifolds, but, in their place another form of pipe seems to be attaining a certain popularity, namely, the "T" pattern, in which the main pipe is placed in the center and fed by leads from each end. While this is not so grossly undesirable as the enclosed variety it cannot be commended as sound practice.

In the type of pipe shown in Fig. 1, with which a few engines are fitted, consider the alternate firing orders—

1-2-4-3 and 1-3-4-2. In either of these cases two successive explosions will always come down the right and left branches respectively and interference will occur.

The first effect of this will be that the obstructed pair will be more vitiated by residual carbon dioxide and their fuel supplies arrive in a coarser and less combustible state than the other pair, and the final effect will be that one pair will require a richer mixture than the other.

The leads from all exhaust valves, both inside and outside the cylinder casting, should be of identical dimensions and internal shape and should enter the main tract or merge with each other at an acute angle, the apex of which points in the direction in which the gases are moving, as in Fig. 2. By this means only can identical degrees of scavenging be assured, assuming similar valve timings.

Now, while the "T" pipe is not good practice, the same is not necessarily the case with the "Y" pipe; especially a 4-port "Y" pipe. Considerable care, however, must be exercised in designing the curves. Note, for example, Fig. 3. It will be obvious that absence of interference is by no means assured here. The port leads enter the respective branches at the desired angle, but the angular relations in which the two branches themselves stand are clearly too obtuse, and interference as indicated by the dotted line will in all probability set in.

It would seem that a two-port arrangement is wholly inadvisable, for, in almost every instance observed there is evidence of interference according to the firing order as above; and a careful inspection of the single port system will readily show how this can well be so. At the critical scavenging point of one cylinder comprising the pair, the succeeding one in the order of firing is almost at full blast, and in a comparatively restricted area when no particular direction has yet been imparted to the exhaust gases. It is inconceivable that interference will not take place. All experiments go to show that this is one thing to be guarded against.

The highest grade of English engines is provided with external manifolds of the general design shown in Fig. 2, or alternatively on the lines of a deep Y, which is equivalent from a functional standpoint.

#### Inlet Manifolds

With regard to the inlet design, it must be admitted that British makers are by no means happy, especially where six-cylinder engines are concerned.

The main functions of an induction system are to provide by suitable dimensioning a maximum and if possible a constant peak velocity at all points from the carburetor to the valves, consistent with the maintenance of volumetric efficiency, having regard to the horsepower curve required, and to avoid corners, pockets and any local enlargements that will produce depositing whirls and eddies.

Where four and six port engines are concerned and appearance and expense no object, the unidirectional "figure 8" manifold (Figs. 4 and 5) with two carburetors seems to be as near perfection as any that have been tried, gas shock being apparently reduced to a minimum and the utmost steadiness of current assured. But cost, appearance and mechanical inconvenience place these designs quite outside the pale of the ordinary production job. We are obliged, therefore, to try to obtain similar results by less cumbersome and expensive means and must choose between an external manifold of simple design and the internally cast induction system.

In either case experience shows that the prime necessity is constancy of area. Where angles or bends are employed, they should be so designed as to impose an

identical number of deviations of the same angles between the carburetor and each inlet valve. This is easy enough to do in the case of a four-cylinder engine by means of the ordinary "T" or "Y" pipe, and it would seem that there is little difference in the respective efficiencies of these designs provided one does not ignore the internal disposition of the valves in relation to the port, in engines where there are two cylinders per port. In such cases it is desirable to avoid a large space of nondescript shape inside the port, for, although located within the cylinder casting and subject to the surrounding heat, this space is virtually still the induction pipe and, with the present low volatility fuel, deposition can easily take place.

Again, it is generally found to be better where a wide "Y" pipe is used, to straighten up the ends before approaching the ports, for the reason that otherwise deflection can easily occur at high speeds, and the outer pair of valves receive by centrifugal action more than their due share of the heavier parts of the charge.

#### Surface of Manifold Interiors

It is usually considered that internal roughness of the induction tract is inadvisable unless the surface is well heated, as in the case of the cast-in manifold, the reason being that the rate of movement of that portion of the charge adjacent to the rough walls is reduced by skin friction and a depositing tendency set up.

Certain research authorities are said to have found that the section of moving charge illustrated graphically may be represented by a parabola when moving at a comparatively low rate; as the velocity of the moving mass increases the top becomes flattened into a series of small parabolas until, at maximum velocity, these span the distance from wall to wall, with the exception of a small annuli near the actual surface of the tract, which is always at low speed (Fig. 6). The richness of the mixture is said to be such that the minimum of fuel is in the center and the maximum at the outside.

It appears from actual experiment that with the cast-in manifold the heat of the surroundings neutralizes to a great extent the depositing effects of surface roughness, for, in respect to economy, there is little difference to be noted.

For high volumetric efficiency purposes, however, there seems little doubt that the external pipe is the better. Hot surroundings are undesirable in this case owing to the volumetric losses which accompany a heated charge and conversely a smooth interior is essential.

#### Six-Cylinder Gas Distribution

One of the greatest troubles in the design of induction systems is the question of distribution in the six-cylinder engine. Ever since the inception of this design this has been a much debated point. The principle of employing two carburetors on high-grade productions seems to have more or less solved the problem.

Strangely enough a perfectly straight pipe with a horizontal carburetor at each end (Fig. 7) has been found to answer very well indeed on certain engines despite the apparently well established theory that unidirectional flow is desirable. On the other hand, at least one well-known French maker employs very successfully a straight pipe with two vertical carburetors feeding into it opposite ports No. 3 and No. 4 (see Fig. 8). An over-rich mixture to these cylinders and starving of the end pair with such an arrangement would be expected, but in practice it seems to work well. No doubt the troubles foreseen for the middle pair are prevented by the spreading effect of the right-angled bend imposed upon the gases on leaving the carburetor; but it is difficult to

see why the rebound and consequent gas shock at the ends does not play havoc with the distribution.

The only thing that we seem to have established with certainty is the futility of having an acute angled supply to one port, or pair of ports and an obtuse bend leading to the others. Apart from this it is painfully evident that we have still much to learn regarding the subject of distribution, and it is needless to emphasize the importance of this matter, for bad distribution must inevitably cause waste.

### Combustion Chamber Design

The relation of combustion chamber design to thermal efficiency must receive attention. The desirability of smallest possible metallic area exposed to the flame and of reducing the heat absorption to a minimum by machining and polishing of the head are well understood, but some of the more recent researches into the question of charge turbulence and detonation, which have lately been occupying the attention of European investigators cannot fail to be of interest, as they have a great bearing on fuel economy.

It has long been obvious that in order to permit of the pressure developing at a suitable rate to exercise a useful driving action on the piston crown the propagation of flame throughout the charge must take place at a considerable speed, and the original impression was that it increased by a definite and high rate of acceleration. It is now established, however, that the rate of flame travel in a still charge is a fixed figure and is in the neighborhood of  $7\frac{1}{2}$  ft. per sec.

The establishment of this fact led to further investigations, with the result that the spread of flame is now known to be solely dependent upon the mechanical action of the whirling charge which carries it throughout the mass, and that the efficiency of the combustion is therefore directly concerned with the speed of the whirling. The effect of this discovery was, of course, to throw a considerable light upon many points in connection with combustion head and valve design which had previously been debatable, and in some cases completely misunderstood. The superiority of the overhead valve is now seen to be in great measure due to the increased turbulence permitted by the more symmetrical shape of the head.

### Detonation

So far as our present knowledge goes detonation appears to be produced as follows: While at normal temperatures and pressures the progression of the flame of combustion throughout a mass of charge will be at a speed which depends upon the rate at which it is mechanically carried by turbulence, there is a top limit to the temperature at which this gradual propagation can continue. When, owing to various causes this critical point is exceeded, the mass, or portions of the mass, so raised will spontaneously ignite throughout its bulk, giving rise to an exceedingly sudden and very high pressure, which is of no driving value whatever and represents so much wasted fuel. In its more advanced stages this action is so momentary and violent that it imparts practically a hammer blow to the cylinder, causing molecular movements in the wall which are popularly described as "knocking." By means of high speed cinematography the cylinder can actually be seen to "breathe" under the influence of violent knocking and only the very momentary nature of the excessive pressure saves it from disruption.

Having regard to the predisposing cause of this trouble, namely, heat, it is not hard to follow the stages of its development. As the first portions of the charge are

burnt at their normal rate the resultant pressure is communicated to the residue, raising its temperature. Should the original temperature of the unburnt part be already unduly high owing to the heat of its surroundings it is easy to realize that its critical point can readily be reached, and it will further be evident that the higher the original temperature of the gas the greater will be the proportion of the residual bulk that will detonate.

Keeping in mind these two primary facts in regard to charge turbulence and detonation, a very interesting line of thought is opened, for it will be evident that the shape of the combustion head has a marked effect on both. The more rapidly we can whirl the charge the more homogeneous will be its temperature, and from this it naturally follows that as the speed of turbulence depends largely upon the emplacement of the valves and the symmetry of the head, the presence of valve pockets, unless carefully placed in relation to the main chamber, will act as local hot spots and stagnant areas, the contents of which will probably attain a degree of heat well in excess of the mean temperature of the charge. In practice this theory is well borne out, for it is known that the overhead valved engine is much less prone to knock than either the "T" or the "L" headed types, and that sleeve valve engines are particularly free from this trouble.

### Equal Distribution of Heat

The lesson which is learned from the establishment of these principles is that the prime objective is not so much keeping down the mean temperature as distributing the heat equally over all parts of the combustion head. It is much more difficult to do this in an L or a T head than in an overhead engine, and conversely it is easier to accomplish in a sleeve valve type than on either of the others.

It would appear from experiments that the exhaust valve itself is the principal cause of local overheating. A certain racing "L" head engine having a compression ratio approximately 7 to 1, once used at Brooklands, could be driven to a standstill on a hill without changing down and with scarcely a sign of knocking in evidence. The secret of its ability to perform this remarkable feat was that its exhaust valve guides were drilled with a small channel through which a fine spray of water was directed on the under side of the valve, which was thus kept cool. Such an arrangement would, of course, be quite useless for standard production work, but its effect on the functioning shows very clearly how great is the necessity for avoiding local hot areas. In those days the principles of detonation were unknown and the success of the scheme was erroneously attributed to the prevention of pre-ignition which, as we now know, is quite a different thing.

What is the most economical shape of combustion chamber from the fuel consumption standpoint? There can be little doubt as to the reply, namely, that with overhead valves. Here we have a combination of all the desirabilities—minimum of exposed surface, maximum reduction of local hot spots, the most direct entrance and exit for the gases, the most favorable shape for charge whirling, no possibility of stagnant charge areas, and last, but by no means least, the capacity in virtue of the above advantages to use a much higher compression than would be possible in the "T" and "L" heads without detonation losses, for it must be remembered that thermal efficiency rises directly with the compression ratio provided partial detonation does not set in.

There is much misapprehension in England regarding the utility of high compression.

An L or T head engine on which the compression can be successfully raised must be so dimensioned that, (1) the piston does not rise appreciably above the floor of the valve pockets, (2) and that there is still a suitable space in which the charge may whirl. The isolation of a large part of the charge in a valve pocket which would result were the piston brought very near the roof of the combustion head is obviously undesirable.

While the functional superiority of the overhead design is recognized it is well to see in what way the L head as such can be improved.

#### Detachable Cylinder Heads

One of the most useful innovations in this direction originally introduced in America, and subsequently adopted in England, is the separate combustion head.

Apart from its convenience from a production point of view, this principle has certain functional advantages which justify its development; (1) it enables the inside of the head to be machined more easily, (2) it permits of better heat distribution owing to the absence of the uncooled masses of metal forming the valve caps and (3) it allows a better choice of places in which to put the spark plug.

The advantages of (1) have already been dealt with. As to (2) it is occasionally argued that the valve cap masses are merely eliminated at the expense of the introduction of other masses. While this is perfectly true it must be remembered that other masses, for example, the thickenings necessary for the anchorage of the head, are much less unfavorably placed as regards their effect in producing local hot areas, which is, of course, the chief objection to their presence. The position of the plug is also important. Its position determines to a great extent the direction of the flame whirl. There is little that can be done as regards positioning on a theoretical basis. By using trial and error methods in the individual case it will be found that in some locations detonation is much less in evidence than in others.

The advantages of reducing tendencies to detonation are important. It is not the mere fact of freedom from knocking which counts, although that in itself is a great acquisition from a standpoint of comfortable driving. It is rather the ability to employ greater compressions that matters. Compression is one of the most potent factors in economy, provided it can be raised without causing detonation.

#### Carburetion

It remains now to deal with the question of producing a proper charge. There are remarkably few engine designers in England who ever attempt to understand the seemingly inconsequential manner in which carbureters demand extremely varied choke areas, induction depression values and air-gasoline orifice ratios.

In France the position taken up by designers is much more logical than in England with regard to the question of carburetion. There it has recently become the custom with many manufacturers when preparing the drawings for a new model, to consult carbureter specialists on those points of design which are directly concerned with carburetion; for example, the induction and exhaust system, the valve timing and certain details concerning the shape of the combustion chamber are submitted for criticism. But in England, with few exceptions, the design of these parts is undertaken without any reference to specialists on this subject, with the result that many engines fall short of the thermal efficiency figure which is merited by their design in other respects. There exists an erroneous impression that the carbureter is in the nature of an independent accessory,

instead of being one of the most important details of the engine and intimately interconnected functionally with those parts which the designer is apt to regard as purely mechanical or productional propositions.

#### Disintegration v. Vaporization

To analyze the requirements of the engine and consider the respects in which an average carbureter is capable of satisfying them, consider first the state in which the fuel must be delivered. The prime requisite here is intimate admixture with oxygen, hence the necessity for fine disintegration. Could this be carried to a sufficiently advanced state, heat would be neither advantageous nor desirable, for the thermal efficiency of an engine depends upon the amount of oxygen that can be usefully employed—that is, at the necessary speed with a minimum of free or partially cracked fuel in the exhaust. Assuming, therefore, that the fuel can be sufficiently disintegrated by purely mechanical means the presence of heat would be undesirable in that it must cause volumetric losses owing to (1) charge rarefaction and (2) displacement of oxygen, which must follow upon a partial vaporization of the fuel, for the smallest possible space is obviously occupied by disintegrated but unvaporized fuel.

While these conditions can be approached at very high induction velocities combined with an engine regulation and design which give the utmost freedom from depositing pulsations, it is clearly impossible to fulfill them at low velocities. We must, therefore, fall back on heating, which is the only alternative measure.

The degree of heat is of considerable importance, for whereas too low a temperature will permit of the fuel entering the cylinder in an insufficiently pulverized state to insure that it is completely and quickly burnt, too high a temperature will cause unnecessary rarefaction.

Careful experiment shows that the essential degree of heat varies considerably in different engines and conditions of carburetion; but it would seem that the heat applied should be such as to give the charge a final temperature of 90 to 100 deg. Fahr.—that is, in the induction pipe, after the latent heat losses have already taken place.

Apart from the question of induction heat the general engine temperature itself has a considerable effect upon economy; an over-cooled engine is well known to be a great fuel waster.

There is a critical engine temperature at which the thermal efficiency is at its best, and for economic results a means should be provided to enable this point to be maintained, for example radiator shutters or thermostatic control of the water circulation.

#### Heating the Carbureter System

As for heating the carbureter system there are two ways of accomplishing this adopted by British designers, namely, by hot air obtained from an exhaust muffler and by jacketing the induction pipe in cases where the manifold is external.

The latter method is generally considered the more accurate, for the two reasons that (1) there are less volumetric losses and (2) the degree of heat is more constant, for, in this connection, it must be remembered that the exhaust manifold is very greatly influenced by such factors as load, spark advance and mixture strength. Admittedly, water circulation is also affected by these irregularities but to a relatively slight degree.

The next matter for attention is the actual production of spray, and here carbureters fall very short of practical requirements. While at high engine speeds all may be well, in touring practice the wide-open throttle con-

dition to which this figure applies is only occasionally attained; medium and low-throttle positions are much more frequently used, and in these conditions of driving the carburetor is found wanting, first for the reason that its spray-producing qualities are not constant throughout the throttle curve, and second because it is in the majority of cases quite accidental if the instrument suits the characteristic of the engine.

The point of maximum velocity is at the opening edge of the throttle until such times as its progressively increasing area becomes equal to or greater than the choke area, in the case of open carburetors with a variable vacuum. The main jet situated in the choke is not operating to its fullest advantage until the throttle is well opened, while the auxiliary jet, which is placed either at the edge of the butterfly valve or in the case of a barrel throttle, generally near the center of the barrel, is not at any time the point of maximum velocity.

When a butterfly throttle is used part of the air goes round the other side of the disk, thus reducing the local velocity; while in the barrel type there is a high velocity point at its top and bottom closing edges, but comparative stillness in the intermediate area in which the jet is placed.

The best design would incorporate a variable venturi with a perfectly controlled jet in its waist. This presents very great mechanical difficulties, however, for the jet must be dually controlled, that is, it must be mechanically variable to conform exactly to the extreme variations of the velocity in the venturi, and must also be controlled for automatic correction to deal with variable loads and speeds at constant throttle positions.

#### Carburetor Characteristics

It is, however, in respect of their "characteristic" that carburetors are principally found wanting. A constant mixture at all speeds is not desired. Note the diagram (Fig. 10) showing an average throttle curve chart. The air-gasoline ratios are shown on the left and the degrees of throttle openings at the top.

Taking now 15.3 to 1 as the perfect combustion ratio it will be seen that for easy starting and slow running the fuel proportion is a little high, but as the throttle opens a weak area is shown from about one-eighth to three-eighths opening, namely, in the average driving position. For purposes of acceleration, however, which is usually done at half to three-quarter throttle, the mixture is chemically correct; but for extreme power, at the last fraction of opening, the proportion of fuel is increased about 25 per cent.

The necessity for the last-mentioned enrichment arises from the fact that a chemically perfect ratio is not the most powerful. Owing to the specific heat changes at the high temperatures of combustion it is found desirable to increase the percentage of fuel by about 25 in order to keep down the flame temperature and thus gain a few per cent of extra power, not through improved combustion, but due to cooling effect of the latent heat of the additional fuel. It will be obvious that this addition must only be made at the very last fraction of opening and thus be used solely for emergency purposes, where extreme power is desired.

Apart from the fact that there is no carburetor on the English market in which means are provided to shape the throttle characteristic as desired, that of the engine is itself a variable quantity and complicates still further efforts to balance the two curves.

The difference in the inertia values of air and gasoline is important. The former being light will readily respond to varied impulses, but the latter because of its much greater weight will follow them less readily. Con-

FIG. 9

Fig. 6—Graphic section of induction current, showing effect of increased velocity. Fig. 9—Diagram showing the throttle mixture curve suitable for an average touring car engine

sequently, the more pulsating the current the larger is the jet or, as the case may be, the smaller the choke necessary to give a stated mixture.

If, therefore, we have a well-considered valve timing, strong valve springs to prevent lag and bounce, and an intelligently designed induction and exhaust system, we can count on a fairly straight engine characteristic. But where there is any tendency to variations in the nature of the periodic impulses troubles commence.

An engine designed for very high output at high speed has exhaust inertia, a big overlap of inlet and exhaust valves, and a steady current which will advantageously take a large choke results, but at low engine speeds there will normally be insufficient spraying velocity at the main jet, consequently a flat area will develop here unless the throttle is placed near enough to the choke to take over its duties to an extent pending the attainment of sufficient air speed in the latter to permit of its functioning unassisted. Lowering the throttle would cure matters were it feasible.

On the other hand, if the throttle is, as is frequently the case, too near to the choke, the proximity of its opening edge to the jet will cause the latter to function too soon and give rise to a rich area in the throttle curve at a point of partial opening which is difficult to eliminate.

The correction cannot be done at the auxiliary jet in either of these cases, for this would, in turn, upset the curve at small throttle openings. One solution is to have a main jet of some type in which the correction does not start until this point is passed, and this is difficult to secure in the case of constant vacuum carburetors where the jet is automatically controlled by a taper needle set in the gravity valve and moving therewith.

Consider next the case of the engine in which the exhausts close early, but which have springs of sufficient lightness to allow the valves to develop a progressive lag as the speed increases, and thus eventually close by accident where they should have closed by design. It will be quite evident that the result of such an unintentional variation in the valve timing will be to provide a jerky current at low speeds which suddenly steadies as the automatic closing lag sets in.

Imagine a set of circumstances such that the current will be steady at low speeds and gradually develop periodic vibrations as the speed rises. A badly designed exhaust manifold, for example, will have this effect, or a combustion head so designed that there is a great predisposition to knocking and, therefore, a late ignition is essential. The inevitable effect of a late spark is that the explosion will be slow in developing and the residual pressure will, therefore, become progressively higher as the speed mounts up, and from this will naturally follow a periodic vibration which will rise in intensity directly as the residual pressure. In this case, instead of requiring mixture correction, we need a gradual enrichment to balance the inertia disturbances offered to the gasoline column in the spraying member, and this, of course, is not a condition normally cared for by any standard carburetor.

It will thus be evident that a large number of different engine characteristic curves can readily be arrived at by various combinations of defective details of engine design; that is, in respect of induction and exhaust tract and combustion head shapes, valve spring strengths, cam contour, etc. If the different proportions of mixture demanded by the engine with increasing speeds happen to be within the capacity of the correction device of the carbureter, all may be well; but otherwise the instrument is called unsuitable, whereas the real facts frequently are that the engine designer, through lack of knowledge of the more intricate side of engine functioning, has imposed a set of conditions which no ordinary carbureter could possibly be expected to deal with in a satisfactory manner.

### Ignition Timing

Ignition is another question which seems to be insufficiently studied; that is, in its relationship to the carbureter. The average engine should take at medium speeds an advance of about 30 deg., assuming a normal magneto or any other form of ignition which maintains its spark intensity at high speeds, and which does not develop a progressive lag as the speed increases. In badly designed combustion chambers, however, where there is a great tendency to detonation on increasing the load, the ignition timing is often made unduly late to prevent knocking. This always leads to complications,

for residual pressure is almost sure to develop above a certain engine speed, assuming a large throttle opening and load, and thus the carbureter becomes the scapegoat for faults which are directly due to some fundamental error in design and not attributable to this instrument at all.

The measurement of fuel consumed per brake horsepower-hour as determined by bench tests should be conducted both on a basis of load variation and throttle variation at constant and at varying loads. In this way defective characteristics can be located and traced where an ordinary load curve would disclose nothing.

The average modern instrument of reputable design is quite capable of dealing with all ordinary engine characteristics if correctly adjusted. When it fails to do so it would be well if engine designers would consider the probability that all is not well with the engine and investigate accordingly, instead of unequivocally writing off the carbureter as defective and searching for one which is able to deal with abnormalities. For, as can readily be appreciated from the above examples of abnormal characteristics, a carbureter which will suit such an engine where others of repute fail will, in many cases, simply mean that, far from being a first-grade instrument, it is in actuality quite defective from a point of view of standard requirements, and eventual troubles are probably in store for an engine passed out on the former assumption.

## A Viscosity Temperature Chart

**A** CHART for determining the viscosity temperature relation of various mineral oils is given in the accompanying cut. By the use of this chart it is possible, according to *Lubrication* in which the chart is published, to determine, if the viscosity at two points on the curve are known, the viscosity at any other point on the temperature scale, since for all mineral oils the lines on the chart are straight, at least above the temperature of the cloud test.

Oils A, B, C, D, E and F, which are all straight-run distillates from the same base crude and differ but little in gravity, have lines which are almost parallel. Oils N, P and U, which differ considerably in gravity, being from a different crude, have lines of different slope.

Below the temperature of the cloud test, the viscosity rises rapidly, due to the precipitation of the paraffine, and the curve turns upward. In well-refined naphthene base oils, A to I inclusive, there is practically no paraffine content, hence it will be noted that there is no deviation from the straight line.

Chart showing relation between viscosity and temperature of various mineral lubricating oils

**A** RECENT U. S. Consular Report makes the following statement as regards motorcycles in Australia:

"The average price of a motorcycle at present in Melbourne is \$826. In 1911 it was \$315, and in 1914, \$365.

It appears necessary for every motorcycle to have a side car, which costs \$207. Apparently it is now cheaper to purchase a second-hand motor car than a fully equipped motorcycle."

# How an Effective Labor Policy Has Increased Production

The most important factors of human relationships in industry are those which cannot be photographed or charted. The successful labor policy discussed has recognized that fundamental fact and has proceeded along sound production lines. A carefully planned wage system is a feature.

By Norman G. Shidle

THE journalist often speaks of going out to "dig up" a story. The expression indicates that he must make special effort and inquiry to locate the material desired. It often happens that the story most difficult to "dig up" is the best story on the particular subject. This is specially true in the field of labor and industrial relations. The story that is easiest to find and easiest to write is that which deals with definite schemes and plans, that contains formulas, brass bands, pig roasts and other perfectly tangible things, pictures of which can be shown and diagrams drawn.

But the difficulty with such stories is that, because of these very tangible characteristics, they deal with the superficial rather than the fundamental factors of human relationships in industry. The fundamental factors are intangible to a large extent; they deal with the feelings and actions of individuals and the reasons for those actions and desires. The factory in which the management has caught the vision of these fundamentals and in which the labor policy is being worked out along basic lines may have few surface indications of a "story" at all. And even when the facts are discovered it is no easy task to reduce to common terms the psychological and intangible factors involved.

Since such factors are fundamental, however, and are essential to the understanding and operation of any labor policy, a discussion of a particular plant in which definite progress has been made is always of value. Through a study of various individual instances, each of which is developing along constructive and permanently progressive lines, it may be possible to build up a philosophy and a series of principles for practical application which will solve the labor problem for those making the study.

The methods in use at the Autocar plant are worth attention from this point of view. The interesting feature of the work at this plant is not so much the detailed working out of methods as the excellent results achieved through a working out of general ideas based upon sound fundamentals. The methods revolve around several basic factors, the chief of which may be listed as follows:

1. A carefully planned, installed, and operated method of wage payments
2. A successful promotion policy
3. A definite effort to develop leaders
4. Some study of monotony work and attempt to reduce its detrimental effect upon the individual
5. A broad vision of the labor problem in general and an intelligent conception of the relative importance of the various factors involved
6. A realization of the necessity for slow growth in the development of a labor policy.

7. Belief that ultimate progress in industrial relations depends upon an understanding and proper handling of the individual.

## Wage Payments

The striking thing about the system of wage payments in use at this plant is the care with which it was installed. The system itself is a form of bonus payment similar to that often found elsewhere. The payment of bonus rests upon a time and piece basis. The man is paid a certain base rate. Then a task is set. When the man accomplishes 90 per cent of that task his bonus begins. The bonus then increases in certain definite proportions as the production of the man increases.

This system, it is obvious, rests fundamentally upon the establishment of accurate times for the performance of the various operations. This company recognized the great trouble which might occur from the setting of inaccurate task rates. It realized that every change in rate is a cause for suspicion in the minds of the workmen. For this reason it went about the setting of task rates very slowly and very carefully.

The management decided some two or three years before installing this bonus system that the system was to be used. Then work was begun in gathering data, making tests and experiments, correlating material and checking up results. In other words, every reasonable precaution was taken to make certain that all the task rates set should be accurate.

The man in charge of task setting and bonus work is a former shop man in whom have been developed the qualities other than mechanical necessary for such work. This man had worked in the Autocar shop for years and knew practically all of the men as friends before taking up this work. The men liked him and had confidence in his fairness and honesty.

The attitude of the workers toward the man in charge of rate setting and bonus adjustment is always, of course, an important factor in determining the success or failure of any such plan.

When the task rates were finally ready for installation, the bonus system was started in two departments only. The men were told that the sky was the limit on production, and that the task rates would not be increased unless there was a change in design or machine equipment.

For some time only a slight production increase was noticeable. The men had seen systems of this kind operate and had heard of their operation in other plants. They knew that when a statement of this kind was made it did not always mean exactly what it said. They knew

of many instances in which the piece rates had been cut or task rates increased, regardless of what was said at the beginning. So they were cautious in advancing production and were afraid to earn a large bonus.

The management said nothing and made no attempt to drive them, but reiterated its statement that task rates would not be increased. Gradually production increased. Little by little the men began to earn more bonus. Finally it became evident to the men that the management honestly meant what it said and they "went to it." The experience of the men in these first two departments spread to other parts of the plant, of course, and the installation of the system in those other departments was a comparatively simple matter.

The long period of preparation that had been gone through, however, should be recognized as an important factor in the success of the plan. Careless and hastily set piece or task rates have probably been the real cause of more labor trouble than any other single factor. In this plant it took a long while for the management to gather and correlate the data which they considered essential to the proper establishment of rates. But the result has been a permanent benefit to both management and men. This is simply another illustration of the fact that it is not so much the system as the method and spirit in which it is installed and operated that is the chief factor in making for success or failure.

#### Promotion Policy

When men are promoted from within the organization a desire to advance is likely to be common among the employees. Such a policy has been pursued at this plant. Practically all of the foremen have been developed from among the workmen, while the plant superintendent, as well as the production manager, was formerly a workman in this shop. The advantage of this policy is that it presents a definite promise to every workman that he will have an opportunity to rise through increased effort.

There are dangers, of course, to a promiscuous adoption of the policy of promotion from within. The promotions must be made with discrimination and the selection of leaders be on the basis of merit and not favoritism. When a man who has been unpopular as a workman is made foreman there is trouble in store for that department; far more trouble than if an outsider were brought in.

Taken as a general thing, however, the policy of promotion from within is an excellent one, and will go far toward obtaining better spirit among the workmen.

To develop leaders from within the plant, however, is not always an easy task. "There are a few natural leaders," says H. A. Butler, superintendent of the Auto-car plant, "but most leaders have to be developed. There are not nearly enough of the natural leaders to fill all the foreman jobs.

"It is possible, however, by training to develop certain men into leaders. The chief things we try to instil into our foremen is that they are representing the company and that they must, therefore, be absolutely square and honest in all their dealings with the men. Our management never promises the men anything it does not fulfill, and we make our foremen understand that they must carry out this policy to the utmost."

#### Monotony Work

In this truck plant the problem of monotony work has not become serious up to the present time. While there are, of course, numerous routine jobs throughout the factory, production has not reached the large quantity stage. Nevertheless, the presence of the problem is recognized. Superintendent Butler has considered this matter rather

carefully and expressed some interesting thoughts along this line. He said in effect:

"While only a few men are natural leaders, I think the majority of men in our shop desire change. That is, they become tired of performing the same operation over and over again. We had two men on a crankshaft machining job, for instance, not very long ago. One of these men had been on that job for two years. Finally he came to me and said he would either have to be changed to another job or leave the plant. He was seeing crankshafts go round in his sleep.

"We try to watch this sort of thing and not let it get that far. We changed that man, of course, but we usually try to change them before they get that way. The normal man does not like to have his mind dulled and be tied down to doing exactly the same thing in the same way day in and day out. And you can't blame him.

"Once in a while you run into an exception. I told the foreman the other day, for example, to change a man from a Fellows gear shaper job, on which the man had been working for several years. The man had made no kick, but I thought he must be nearly "fed up" on that routine job. So we changed him over to a lathe. Two days later he was in here asking to be put back on the gear shaper. But that is an exception. The average man likes a change and does better work if he gets it; his production is better, both as to quantity and quality, in the long run.

"It might be possible to establish cycles of change for men on certain jobs, routing the cycles in such a way as to progressively improve the man's production ability and worth to the company. That would require years of study and a very careful investigation of all the factors involved. We have not come up against the monotony work problem to a serious enough extent at present to make such procedure feasible."

The men here are encouraged to use their intelligence and are given the benefit of results which they obtain. One man, for instance, was running two automatic machines on the task rate bonus system. As the bonus man passed through the shop one day and happened to speak to him, this workman said:

"I wish I had another machine here. I could run a third machine all right. What would you do if I ran three machines?"

The bonus man took the matter up with the superintendent and it was decided to pay this man as though he were one and one-half men and let him run the three machines. The suggestion was made by the man; the company profited by the increased production and the man was given the entire benefit of his increased production. Such actions as this on the part of a management go further toward gaining confidence and co-operation from the workers than any number of speeches and editorials.

#### Service Feature

Along with these more important fundamentals, this concern has in operation a number of the more usual service aids for its employees. It maintains a dental department, a dispensary, an x-ray department, a company restaurant, an oculist and a legal service. The legal service has proved especially popular with the employees. One afternoon each week it gives advice to any employee wishing it. A practical nurse or matron has charge of the girls' rest rooms. This woman acts as intermediary between the female employees and the production manager, as many situations arise that cannot be taken care of by male foremen.

Resting as they do on the sound basis of the fundamentals previously described, these various employees'

service activities fill a proper and useful place in the working out of the labor policy.

### Results Achieved

Excellent results have been achieved by following out the general principles outlined. Production per man has been materially increased over a period of years. Superintendent Butler is authority for the statement that this increase can be attributed largely to the co-operation of the individual workers and to the way in which the company has handled its labor problem.

In normal times the plant employs about 1300 men, and is running at about 60 per cent of capacity at present. Every effort has been made to hold the old men during the time of depression, and men have been switched from one job to another in an effort to limit unemployment. Neither the base rate wages nor the bonus rates have been cut.

### A Slow Growth

At the present time this company has the confidence and co-operation of its workmen. Some idea of the reasons for this fact have been outlined. There is behind it all, of course, a spirit of justice and a real desire on the part of the management to be on the level with the men. This is fundamental.

There is in the shop an atmosphere of "this is a pleasant place to work" that is caught by even the casual visitor if he stops to talk here and there with workmen. We have discussed this matter of "plant personality" at great length in previous articles, but it must be mentioned again, since it does play its part in helping along

the general problem. Like human beings, every plant has a personality. When that personality is pleasing, relations between management and men are always better. But it must be recognized that these important intangible factors cannot be developed in any plant overnight. The general conception of this labor policy has been built up over a period of at least ten years at this factory. The present state of confidence and co-operation is the end of a long journey. Management and men have proved each other through many practical tests. Suspicions have been overcome, not by short talks, but by continuous actions over a long period of time.

A spirit of co-operation, a true friendship, a community of purpose and thought—these things are not achieved by an efficiency engineer, nor by a series of "loyalty letters," nor by a new bonus scheme or stock ownership plan, nor by baseball teams and summer picnics, nor by any purely material and easily installed or obtained things. They are achieved by a long period of honest dealing, of close study of individual workers, by a thorough investigation of every job in the plant, and by a constantly progressing development of all the factors affecting human relationships in industry.

It may be objected that such methods take too long and are too much trouble. But they are permanent and pay for themselves as the development takes place. The labor expert who offers a sure and quick cure is just as much a charlatan as the patent medicine man of old. The permanently progressive things of industrial success come from careful experiment and hard work and study—in industrial relations as well as in mechanical development.

## A New Aluminum Piston

**T**HERE is much evidence that the aluminum piston is in a new period of development, for new designs are being brought forward constantly. The objectionable features of the earlier designs are fully understood, and inventors are endeavoring to overcome them. The illustrations herewith show a piston manufactured by the Waddell Motor Corp. In this piston the skirt is partly detached from the ring belt and the lands between the ring grooves are turned with sufficient clearance so there can be no trouble from seizing. Only the skirt is depended on for bearing surface. Those portions of the skirt around the ends of the piston bosses are relieved and are detached from the rest of the skirt by saw slots. The bosses connect with the piston head and the ring belt by two substantial ribs running parallel with the piston pin axis.

The skirt is split on the pressure sides by inclined saw slots, but round bosses are cast on the inside of the skirt where these slots come and these are later drilled out and form a springy connection across the slot. The only connection between the skirt and the ring belt is furnished by four shallow ribs extending from the head to the skirt.

**F**INLAND imported in 1920 751 automobiles valued at 31,500,190 Finnish marks, and 264 metric tons of oil and steam tractors valued at 7,211,970 marks. At the present time motor vehicle business with Finland is rendered practically impossible by an embargo decreed on Feb. 12 last from which exceptions are made only in very urgent cases.

Waddell aluminum piston

# A Novel Method of Hobbing Worms

A helicoidal cutter is one of the features of this new method. The action of the hob is in the nature of a progressive roughing and finishing operation. The metal is removed progressively and the cutting action is distributed over all the teeth. This article discusses the process in detail.

**T**HE screw or worm and its mating gear constitute an extremely ancient combination. The compactness and simplicity of design, and the large speed reduction attainable, make it peculiarly applicable to many types of mechanism. When rigidly mounted and properly lubricated, this gearing is noiseless and one of the most efficient means yet developed of transmitting power between shafts lying in different planes.

Worm gearing has not been used in the past to as great an extent as its merits would seem to indicate. This has been due, principally, to two reasons: First, difficulty of producing correct multiple-threaded worms and worms with an excessive helix angle, and, second, inability to successfully produce correct worm gearing of small velocity ratio, approaching one to one.

Most worms are made with helicoidal teeth, and this article will deal with worms having teeth of that contour. The axial plane of a helicoidal worm is a plain, involute rack section, and the teeth of the mating gear, at the central plane, will have involute curves thereon, unrolled from the basic rack.

A single-threaded worm with a moderate helix angle can be successfully threaded in the lathe. The lathe tool used can be set parallel to the axis of the worm, or can be set normal to the tooth helix. In the first case, it would be necessary to reverse the worm after finishing one side of the thread, and then cut the opposite side, due to the impractical cutting angles otherwise obtained on a double-sided cutting tool. When a straight-sided tool is set normal to the tooth helix of the worm, a modified form is produced in an axial plane, and the hob used to cut the mating wheel must be changed to correspond.

With the evolution of the machine tool industry, and the development of machines which in production far outstripped their predecessors, the process of milling worms with a disc cutter was originated. This method answers very well for single-threaded worms, and is much faster than cutting the threads in a lathe.

To obtain a worm with true helicoidal teeth, with straight sides on the linear or axial section, it is necessary to correct the shape of the disc cutter, owing to the interference of the cutter and the helicoidal surface on the worm tooth. This is done by forming a lead or cast iron disc to the proper contour, and using it as a template in making the cutter.

If the above process is not employed, the advantage of having a basic rack section and conjugate teeth on the mating wheel unrolled therefrom is lost. Such a formed cutter, of course, can only be used to thread worms for which its tooth contours were intended. Worms of dif-

ferent diameters, threads or linear pitches require cutters made specially therefor.

The Gould & Eberhardt Co. have developed a novel method of hobbing worms, which is claimed to be as far in advance of worm milling with a disc cutter as the latter was superior to the old process of cutting the threads of worms in the lathe.

The production of multiple-threaded worms by the lathe or thread-milling process, necessitates intermittent indexing motions, either hand or automatic, with their inevitable resulting inaccuracies. The hobbing method, with progressive and continuous indexing, entirely eliminates this objectionable feature.

In the hobbing of worms, either single- or multiple-threaded, a hobbing machine is used with the gearing ratios throughout so chosen that a velocity ratio of one to one is readily obtainable between the cutter and work spindles and the machine operated just as when cutting helical gears.

One of the novel features of this new method of hobbing worms is the helicoidal cutter employed, which also permits worms to be hobbled which have a shoulder on either or both ends.

The hob, illustrated in Fig. 1, possesses several distinctive features. The teeth are arranged in a helical formation similar to gear hobs. There are about fourteen roughing and three finishing teeth. It will be noticed that there are only about one and one-half convolutions of teeth, thus making this hob much shorter than gear hobs, the length being about twice the normal

circular pitch of the worm.

The action of the hob is in the nature of a progressive roughing and finishing operation. The roughing teeth have their tops and sides reduced in regular decrements, starting with the last finishing tooth and ending with the first roughing tooth. This portion of the hob has somewhat the appearance of a spiral. The lowest tooth is made high enough to cut into the periphery of the worm as far as its center line, while each succeeding tooth takes out a little more metal, ending with the finishing teeth, which smooth and complete the worm tooth shape. The arrangement of teeth just described, and the cutting action secured thereby, make this hob analogous to a broach coiled around a cylinder. The removal of metal is accomplished progressively, and distributes the cutting action over all teeth.

If the hob is made in the ordinary manner, it will be found that the following side of the hob teeth will, if uncorrected, cut away a part of the worm tooth from the pitch line to the outside diameter of the worm.

This necessitates a different lead on the two sides of

Fig. 1—Worm hob

Fig. 2—Machine cutting single-thread worm

Fig. 3—Machine cutting seven-thread worm

the teeth, the leading side being made to the basic lead calculated from the normal circular pitch. The following side is recut to a shorter lead, sufficient to clear the theoretical contour of the worm tooth.

When the machine is set up, the middle finishing tooth is centered with the axis of the worm. The roughing teeth lead, and the finishing teeth follow, in the direction of hob rotation.

The production and accuracy attainable with any worm-threading process are to the practical man the outstanding features by which the merits of a given method are mainly judged.

The production possible with the hobbing method is said to be much greater than that which is possible with the late or disc cutter method. This is especially true of multiple-thread worms, as the machine is geared for the number of teeth, just as in hobbing helical gears. This obviates the necessity of indexing by hand and taking a fresh cut through the worm for each tooth, which must be done with a lathe tool or disc cutter.

The accuracy of worms produced by the hobbing method as outlined is said to be superior to any of the other known methods for the reason that in this system the cutting action is progressive and continuous and produces accurately spaced multiple-threaded worms, which is an essential feature in efficient and successful worm drives. The cutting action is a result of the generating characteristics of the machine, and not dependent upon other devices which may be inaccurate or inaccurately operated.

The amount of feed to the cutter and worm blank relatively to each other in an axial direction is dependent upon the helix angle of the worm. That is to say, the greater the helix angle of the worm with the axis, the less the axial feed.

The hobbing method is also adaptable to roughing worms which are subsequently heat-treated and then ground. In roughing with this system the amount of

metal remaining to be removed by grinding is uniform and the spacing of teeth on worm is accurate, permitting a high degree of accuracy in the final grinding.

The fixture for holding the worm blank should be of a very rigid design, with powerful means for driving, because the strains on this mechanism are severe.

Fig. 2 shows one of these hobs mounted in a gear-generating machine finish-threading low-carbon steel worms, single-threaded, of 2.7-in. pitch diameter, 0.666-in. linear pitch, with an output of one every 17 minutes, floor to floor.

Fig. 3 shows the rough-threading operation on an alloy steel, seven-threaded worm, 4.3 in. outside diameter, 4½-in. face, 1.37-in. linear pitch. The time to thread this worm is 60 minutes, floor to floor. The teeth are, of course, ground to final size later.

Another example of production is the threading of alloy steel quadruple-thread worms, 2.8-in. outside diameter, 4½-in. face, 1.06-in. linear pitch in eight minutes each, floor to floor.

Another field in which worm hobbing has proven very successful is in the threading of multiple-threaded automobile steering worms. The worms were produced with very accurate spacing and a good finish. A double-threaded steering worm for one of the well-known cars, of 2.09-in. outside diameter, 1¾-in. face, 0.52-in. linear pitch, has been finished in 15 minutes each, floor to floor.

**A**N abstract report of investigation conducted by the Bureau of Standards on scaling of enamels has been submitted to the Journal of the American Ceramic Society. A co-operative committee of the Enamel Division of the society met at Cleveland on June 20 to consider recommendations of the Bureau for co-operative work, both in the steel and iron mills and in the enameling plants. It is believed that results of the Bureau's work can be put into actual commercial practice through the efforts of this committee.

# Relative Value of Aluminum and Steel as Body Panel Material

The writer believes the field for composite aluminum bodies to be where production is limited to 10,000 or less. This construction is also valuable in the development of new body designs. The pressed steel body is specially adapted to quantity production.

By E. J. Bartlett\*

**T**HE purpose of this paper is not to discredit the use of materials other than aluminum for the metaling of automobile bodies of the passenger type. It is, rather, to define, in a non-technical way, the limitations of the fields for use of the two principal materials used for the sheathing of bodies—annealed sheet steel and sheet aluminum. Any other materials, such as laminated wood panels, cast aluminum sections and the fibrous compositions, are so little used that we may omit them from further discussion for passenger car service, except as occasionally used auxiliaries.

There are three distinct types of automobile bodies, from a constructional standpoint, in every-day use. These are the aluminum composite body, the steel composite body and the all-steel body, using the terms common to the industry.

Aside from the standpoint of quality, which will be discussed later, which of the three types of construction to use is economically determined by just one factor—the quantity produced.

To illustrate, a single body can, naturally, be produced more cheaply by using a wood framework and sheathing it with a ductile metal, such as aluminum, than by the use of a less ductile and more difficult metal to smooth and finish, such as sheet steel. Of course, an all-steel body would be prohibitive.

This same situation is undoubtedly true for ten bodies or 100 bodies or 1000 bodies or possibly 5000 bodies. The border line where the economic use of the composite aluminum body gives way to the composite steel body can be accurately determined for only each individual case where the die cost for the particular design of body can be determined, together with a comparison of labor costs for the two constructions. Somewhere there is a volume point where the composite steel body is the cheaper, and in spite of its disadvantages, none of them vital, economy will compel its use.

For average conditions this point may be conservatively taken at a minimum of 5000 when little regard is given to smoothness and quality, and a maximum of 10,000 when economies of production will probably offset all advantages of the composite aluminum construction. Often in this intermediate field a part aluminum and part steel body is the best solution, as one type of construction gradually merges into the other.

For larger quantities the composite steel body has the field. Here the quantities are sufficiently large to permit a considerable expenditure for dies of proper completeness to produce finished steel stampings. A point

often overlooked is the quality which can be built into steel stampings with proper dies. A cheap die job only passes the buck, as to expense, on to the finishing operations, which to some extent accounts for the seemingly high point where aluminum really gives way to steel in economical production.

The field of the composite steel body is then a minimum of some 5000 to 10,000 bodies with a maximum of perhaps 30,000—the exact quantity governing the change depending upon the design of the body, facilities for building, etc., exactly as in determining the lower point.

## The All-Steel Body

Beyond the quantity of 30,000 or thereabouts comes the field of the all-steel body. Large dies and assembling fixture expenses may then be assumed. An equipment for such work would possibly not exceed \$5 or \$10 per body, and, while this amount might have to be spent in finishing, a speed of production would be attained entirely impossible with composite aluminum construction.

We may then summarize the three distinct methods of body construction about as follows:

Up to 10,000, composite aluminum bodies; 10,000 to 30,000, composite steel bodies; over 30,000, all-steel bodies.

Few bodies are ever built in the quantities first planned without change, and therein lies one of the prevalent false economies of the steel body of either type.

New body types require a period of perfecting and seasoning before they are ready for quantity production. The tendency is to shorten this necessary development through the investment in a die equipment, with the result of an early abandonment of the type or continual dissatisfaction with it.

Aluminum is the ideal metal to use during this seasoning period, as it is cheaper, better in numerous ways and more truly represents, even in small quantities of bodies, the excellence which may be expected in the larger quantities when the dies and stampings are perfected.

The value of this flexibility during the period of stabilizing a body design is often difficult to reduce to a dollar-and-cent basis, although it has a very marked worth. It is to quite an extent the little niceties of a body, not necessarily expensive, which stamp the finished car with an individual sales appeal and, in a close competitive market, assist in making retail sales.

In the foregoing, arguments have been advanced to show why the hand-formed steel panel body has no true field, as from a cost viewpoint it has nothing to recommend it.

\*Vice-President, The Baker R. & L. Co.

When quality is considered, this method of body metaling is at a further disadvantage. Therefore, from both cost and quality considerations composite bodies should be sheathed in aluminum panels until properly pressed steel panels are practical.

Aluminum has the advantage over steel in that, when hand-formed, smoother surfaces and truer contours result. It is easily file roughened and presents a better paint surface, therefore a more lasting paint finish can be applied. It is lighter than steel, although requiring a slightly more extensive wood framework. It is less resonant than steel, hence in an inclosed body lessens drumming. It is more readily repaired than steel, is more

easily welded and is more uniform in welds as to strength and finish. Aluminum is rustproof and requires no rust-proofing treatments, or if paint is scratched through, a wound does not occur which gradually spreads, due to rust. Bodies in storage do not rust when sheathed in aluminum.

Some of these advantages of aluminum panels are offset by the single advantage of steel panels—their additional strength. Where the volume of bodies of a fixed type make steel die pressed panels practical from a cost standpoint, the relatively minor advantages of hand-formed aluminum panels are not essential to a satisfactory body product.

## Some New Automotive Parts

### A Pressed Steel Tire Carrier

A TIRE carrier recently introduced on the market is so arranged as to be interchangeable with the dummy hubs used to carry spare wire or disk wheels. This permits the car manufacturer to mount a standard carrier support bracket on each car as it moves forward in production. If the car uses wood wheels as regular equipment, the carrier is bolted to the face of the bracket, whereas if disk or wire wheels are to be used, the car maker bolts an ordinary dummy hub to the bracket.

The Oakes tire carrier with lock to prevent tire theft

The carrier is made of pressed steel parts riveted together. It requires no straps or fittings to hold the tire rim firmly in position, a simple rim clamp of conventional type being used on the lower arm of the carrier, and the tire is readily mounted or demounted by unscrewing or tightening one nut. The carrier is made in a wide variety of wheel sizes to fit all demountable rims and in single and double carrier styles.

As optional equipment a locking device, shown in the illustration, is installed in the lower arm of the carrier. It comprises a rim wedge-clamp integral with a barrel-shaped casting which has a circular lock flush with the outer face. This device serves to prevent unscrewing the nut and demounting the tires. The lock is firmly held in the housing by its two lugs which expand behind the circular flange, yet it is easily removed from the housing by using the proper key, after which a socket wrench is used on the clamp nut which holds the tire. The carrier is manufactured by the Oakes Co.

### Transmissions for Speed Wagons

ONE of the chassis components that has had to be redesigned to meet the new requirements arising from the use of pneumatic tires on trucks is the transmission. In order to take advantage of the possibilities of the pneumatic equipment in the way of higher speed, the final drive reduction ratio must be kept small. But this calls for a high low gear reduction ratio in the transmission, as the low gear ability of the truck must be maintained the same.

Two transmissions of the unit power plant type, for speed trucks, have been developed by the Warner Gear Co. and are now in production. They are suitable for

trucks of  $\frac{3}{4}$  to 2 tons capacity.

One model carries a reduction of nearly 4 to 1. In the other design, the reduction is nearly 5 to 1, a new development in three-speed transmission design.

Double row bearings at the main shaft rear take propeller shaft thrusts. Different length control and brake levers are available. The clutch is of serrated tooth, multiple disc design. The housing is cast iron. An opening is provided for a tire pump or a power take-off attachment.

### New Design of Circulating Pump

THE weakest part of the ordinary circulating pump is undoubtedly the shaft packing, which often becomes leaky and requires repacking. This is largely due to inefficient lubrication. A new design of pump intended to overcome these troubles has been brought out by the Arrow Pump Co. This pump employs oil lubrication by the so-called ring oiler method and has the packing at the inner end of the bearing instead of at the outer end. The sectional view herewith shows the arrangement. At the present time the bearings of circulating pumps are lubricated with grease by means of compression grease cups. The bearing of these pumps is next to the water chamber and the packing at the outer end of the bearing. This is open to the objection that the hot water is likely to get into the bearing and cause it to rust. Moreover, any foreign matter in the water, such as scale from the water jacket, sand, etc., may find its way into the bearing and start cutting. The new construction, in which the packing is on the inside of the bearing, is said to make it impossible for water and sand to get into the bearing, thus prolonging the life of the bearing and obviating the need of frequent repacking. A metallic, non-abrasive type of packing is used. The packing gland also forms an oil reservoir, thus permitting of the use of the ring method of lubrication.

The Arrow circulating pump

# The Trailer's Place in Transportation Merchandising

## Part II

This second article discusses the problems of dealer representation in the trailer field, together with the difficulties of truck makers adding a line of trailers. Mr. Perry believes the factory branch system best for trailer marketing, but shows it to be a heavy burden.

By H. W. Perry\*

IT has been suggested that a large truck company might undertake the production of a line of trailers and their distribution through its own branches and dealers. There have been intimations that this has been contemplated. Such a policy has its logical aspects. The truck factory, of course, has all the facilities for economical manufacture of trailers and has stocks of parts and materials suitable for the purpose. The work is very similar to truck manufacture and, with the factory operating far below capacity, it would be easy to begin making trailers. The company would have an immediate outlet through its branches or distributors and its established dealers, as it might force them to contract for a certain ratio of trailers to trucks. So the idea has its allurements.

But, while such a method might be successful, there are some important factors that militate against it. In spite of the similarity of manufacture there is an essential difference between the truck and trailer. The truck is a standardized product, designed as a compromise to meet general rather than specific hauling requirements and the factory is operated on the system of quantity production of a few standardized models. Trailers, on the contrary, have been evolved to fill the gaps left by motor trucks and to meet a wide variety of special uses. There has been no standardization of trailers and even the largest trailer companies feel under compulsion to produce as many as twenty or more different types and sizes.

According to the particular work to be done, there must be four-wheel trailers, semi-trailers, pole, pipe or logging trailers and two-wheel balanced trailers. Each type must be made in several sizes and some of the types in several forms; for example, the four-wheel type is furnished in straight frames for ordinary trucking and in drop frames for side-dump bodies. Both the four-wheel and the two-wheel types may have to be supplied with hinged frames to permit of rearward tipping for discharge of loads of lumber. Some semi-trailers require platforms that are very low at the rear end to facilitate loading and unloading of cotton bales, heavy cases or hogsheds.

Thus it will be seen that there is as much variety in the manufacture of trailers as in that of truck bodies, and the demand for any one model is so limited as to make it almost impossible to get into quantity production on a systematic basis. The same reasons that caused

truck companies to forego the building of bodies will keep them out of the trailer field. Special jobs disarrange the factory system, cause annoyance and are seldom profitable. A truck company embarking in trailer manufacture might decide to produce only a few standardized models, but would soon find that these would not meet nearly all the requirements of purchasers of its trucks and would have to add more models or let the customer go elsewhere. All considered, the truck manufacturer would do better to capitalize the development of trailer transportation by adding road tractors to his line of standard trucks.

### Selling Differences

There is even more difference between the selling of trucks and trailers than in the manufacture of the two lines. Neither factory nor dealers would know in advance what relative numbers of trailers of different types and sizes could be marketed with a given number of trucks. The sales records of leading trailer companies show curious fluctuations in demand for different types and sizes from month to month and year to year. The market is still unsettled. Trailer makers themselves have not yet been able to determine to their satisfaction what types and sizes will be in greatest demand and most profitable. And even with a wide-open field the manufacturers individually are not producing and selling in large numbers. A truck company entering the business would not have as broad a market as a trailer company, because its sales would be confined largely if not entirely to users of its own make of trucks. Other truck companies and dealers would not send a trailer customer to a competing truck company or dealer but would naturally recommend to their customers the trailers made by an exclusive trailer company.

A glance over the brief history of the trailer industry indicates that the manufacture of trucks and trailers by the same company has not been successful. A number of companies that began the manufacture of both have dropped one line or the other and it is believed that today there is not a single company actively manufacturing both lines.

Some disposition has been shown for a truck company to tie up with a single trailer company to handle trailer sales through its dealer organization. This is open to the same sales objections as already mentioned and to the further obstacle that unless the trailer company makes a very complete line of all types and models, the organization will not be in position to meet all demands

\*Recently general manager of the Trailer Manufacturers' Association.

of its customers. An arrangement of this kind would be more advantageous, however, to the truck company than to the trailer maker, since buyers of the truck could go into the open market for trailers, but the trailer maker would be limited in sales principally to users of the one make of truck. The owner of any other make, if he became interested in trailers, would be most likely to consult the man who sold him his truck, and if that dealer did not handle trailers himself, he would either discourage the idea and try to sell him another truck or at best would refer him to some trailer man who did not sell trucks.

Confronted by the various difficulties of marketing their product through the truck trade, the trailer manufacturers have had to seek other outlets. The only way they had of interesting prospective purchasers and informing them of the merits of trailer transportation was to get in direct touch with the users of motor trucks. This has been done with considerable success and enough demand has been created in some localities to make dealers eager to take on a line of trailers. It has been necessary, in the larger communities at least, to have a representative sell trailers exclusively or in connection with other lines than trucks. Thus, some of the best trailer representatives are distributors of truck bodies, hoists, loaders, etc., while others handle farm tractors and agricultural machinery, building materials, iron work or other lines. But in each case it is a matter of finding the right man, regardless of his business—a man who can grasp the essential advantages of trailer trucking and has the necessary faith in its future, the ability to convince others, determination to stick to it and wait for profits, and no conflicting interests. Such a man is a valuable find and usually the trailer manufacturer goes as far as possible to help him, sometimes making him a branch manager.

#### Exclusive Trailer Representative

Experience to date indicates that, until the manufacturers have succeeded in educating truck owners generally to the many advantages and economies of trailers, they will find it absolutely necessary to have exclusive representation and to sell direct to users rather than through truck dealers, although they would greatly prefer the latter method. This makes the marketing slow, difficult and expensive and restricts sales promotion chiefly to the larger centers of population. Sales possibilities in the small communities are yet too limited to afford living profits to exclusive representatives, and

without a widespread distribution system, national advertising is ineffective because scattering inquiries cannot be followed up advantageously. This condition will be overcome gradually as trailers become better understood and more extensively used and the attitude of the truck dealer changes. The truck dealer may quickly come to the conclusion, with encouragement of the truck manufacturer, that under present conditions it will be worth his while to sell a line of truck auxiliaries, including not only trailers, but standardized bodies, hoists for dump bodies and other equipment. In short, it will be his function to sell motor haulage equipment, to become an expert in highway transportation and to recommend and sell whatever equipment best meets the requirements of each particular customer.

Lack of understanding and interest on the part of truck dealers has forced the largest trailer companies to establish their own branches in the principal cities and the smaller companies to create very close affiliations with specialty men that result in relations closely approaching those between the factory and the branch. Distribution through factory branches is most satisfactory provided good managers are found because this system avoids all the disadvantages of trying to create sales through motor truck agencies and because intelligent and interested advice and service can be and is given to prospective buyers and actual users.

The matter of service is not very serious where there is a proper amount of interest in the success of trailer installations. In the first place, there is not much in the mechanism of a trailer to go wrong, and in the second place the trailers made by established manufacturers are constructed of parts that are practically standard in the automotive industry, except for relatively few special parts, such as drawbars, couplings and certain steering gear castings or forgings. Bearings, tires, springs and other parts most subject to wear are identical with truck parts. The factory branch can give fairly good service even at considerable distances and smaller towns need not suffer seriously from lack of service. Truck dealers could give excellent parts service in their territory, but good service consists in more than supplying new parts; it calls for supervision of trailers at work, with advice to the user how to get the best results and tactful dealing with drivers who may, for one reason or another, find fault with the trailer.

The establishment of branches involves a great deal of initial expense and they are seldom self-sustaining for the first year or two. The financial burden is greater

Underground storage tank weighing 7 tons hauled with  $3\frac{1}{2}$  ton Army truck and two-wheel pole trailer

Train of steel side dump trailers with loads of ashes at city dump in Indianapolis. The city uses 25 of these trailers for ash removal

than most of the trailer companies are in position to stand, but the tendency is in this direction and it is believed that the branch system will ultimately be the most successful and economical method of distribution. There will still remain, however, the problem of desirable representation in the smaller places. A relatively larger potential market exists for trailers than for trucks in the remoter places, as among farmers, ranchmen and plantation owners and in lumbering and mining regions. Many possible small sales or doubtful fleet sales possibilities in such fields are neglected owing to lack of nearby representation and the time and cost involved in investigating them.

Local representation is therefore highly desirable even if it only serves the purpose of seeking out possible buyers and making first investigations to determine the desirability of having the branch or the distributor send a man to follow up the lead.

### Future Selling Policies

Only time and changing conditions will bring a solution of the problem of merchandising trailers. Perhaps no hard and fast policy will prevail. Probably the best general plan will embrace a combination of trailer branch houses in the principal cities, exclusive representation wherever possible in second-class cities and truck-trailer dealers in smaller communities, provided the truck dealers follow the lead of the truck makers in taking the trailer seriously. As the truck manufacturers continue their investigations and become convinced of the practicability and economy of trailer transportation in various industries and under certain operating conditions, they will pass their findings on to their distributors and dealers and these in turn will co-operate better with trailer representatives in the field. No doubt in time mutually satisfactory arrangements regarding division of commissions will be made between truck and trailer dealers.

At present the truck dealer or salesman who tips off a trailer man on a prospect expects some recompense, but has not yet reached the point where he feels he should give up any part of his own commission on the sale of a truck to the trailer man who digs up a purchaser. There must, of course, be fair reciprocity. Truck and trailer sales will go hand in hand more and more as time goes on. The truck gained great headway over the trailer during the first decade and a half of the twentieth century and there are to-day about 1,000,000 commercial motor vehicles in service in America as compared with an estimated total of 50,000 trailers, based on registrations of 20,000 trailers in fourteen States last year. The bulk of trailer sales will therefore be made separately to present truck owners for some time, but as municipalities trailerize their garbage and ash removal and special indus-

15 ton tractor used by Southern California Edison Co.

tries equip with tractors and semi-trailers or pole or pipe trailers, the power unit and carrying units will be purchased at the same time. Buyers will prefer, no doubt, to deal with a single seller and to make the purchases in one transaction. This will tend to bring the truck and trailer interests closer together.

### Furnishing Transportation

While the interest of the truck and trailer sales managers in this subject is or should be based on the desire to furnish the best means of highway transportation, the fact remains that the former is concerned primarily with the increase in truck sales through the trailer as an auxiliary. He cannot take the same interest in the trailer as in the truck so long as the two lines are manufactured and sold by different organizations. It is through the tractor end that the truck industry will be compelled by force of circumstances to give a great deal of attention to trailers and to advocate their use, as the writer is convinced that eventually most heavy haulage will be done with tractors and semi-trailers—that is, six-wheel outfits. The four-wheel trailer may be expected to find its greatest field of utility in long-distance work, such as intercity hauling, and in operations where road trains of several units will best meet the requirements.

It is most desirable that in all cases the power unit and the trailing unit be suited to each other so as to form a properly functioning combination, but it is not necessary that the two should be made or marketed by the same organizations, any more than in the case of locomotives and railroad cars, or of horses and wagons. But the truck and trailer industries will have to work in harmony and help each other in the common undertaking to make motor transport 100 per cent efficient and satisfactory.

## A Pyrometer Made from a Camera

A SIMPLE pyrometer can be constructed from a photographic camera, according to an article by Dr. Lux in the *Elektro-technische Zeitschrift*. To this end a small box is screwed onto the camera, which takes the place of the plate of ground glass and contains in the plane of the sensitive plate a small incandescent bulb provided with screens. Into the rear wall of this small box is inserted a lens, the ocular of an old telescope or opera glass serving the purpose well. The complete outfit includes also a pocket flashlight battery, a movable coil milli-ammeter and a simple sliding rheostat. In use, the operator focuses the object whose temperature is to be determined, which can be readily done by means of the pho-

tographic adjuster, and then regulates the current sent through the bulb by the flashlight battery in such a manner that the filament of the bulb disappears in the field of the sliding object. The current strength read off at that instant, in conjunction with an easily determined calibration table, permits of reading off the temperature sought to within 2 per cent, as the eye is very sensitive to any differences in the luminosity of the filament and the incandescent body. This pyrometer is suitable for temperatures between 600 and 2100 deg. Cent. if an ordinary osram bulb is used, but can be used also for temperatures up to 3600 deg. if the objective is shaded off and even up to 6000 deg. if a slightly blackened glass plate is inserted.

# The FORUM

## Seating and Other Car Improvements

Editor, AUTOMOTIVE INDUSTRIES:

(1) "The Forum" in your issue of June 16 is very interesting and it would certainly be of great advantage to your readers, as well as of value to your paper, if more of the engineers engaged in the manufacture and design of cars would continue to contribute their views and in the end perhaps succeed in eliminating some of the existing defects of all automobiles.

(2) Of course, each engineer's own design may be perfect from his point of view, but if, as pointed out in one of the letters, before driving and maintaining their own machine they tried out the other fellow's, they should recognize his defects and might, in the end, see that they themselves were not so far behind.

(3) **Inaccessibility.** The first great defect to which all cars are subject is inaccessibility, and this applies to all cars, whether selling for \$1,000 or \$10,000. Apparently the only aim of the engineer is to get the car together and get rid of it, for he knows mighty well the poor purchaser can never get at it if anything goes wrong, and, no matter how trivial this may be, he will have to run it into a service station if he can get it there.

(4) If, on the other hand, as suggested by Mr. Anglada, every designer were compelled to run and maintain his own car for a given time he would eventually see some of the shortcomings, especially if they would put him on an isolated island and give him only the beautiful set of tools usually sent out with each machine.

(5) **Mechanical Defects.** The mechanical defects, of course, will always exist and these are in a class by themselves.

Great improvements have already been made and a full discussion of these in the Forum should be of great advantage and lead to still further improvements, but in addition to these there are many fallacious ideas of details and standards that have been introduced into automobile construction that it is necessary to get away from.

(6) **Body Design.** The matter of seating capacity mentioned in Mr. D. Ferguson's letter, is one of the fallacies or myths of the automobile industry and he is quite right in regard to designing the body for two, four or six passengers and to carry only two passengers on the rear seat, for the automobile has never yet been made that will carry three full-grown persons comfortably on the rear seat. The rear seat will not even carry two and one-half persons as Mr. Ferguson says; three persons of three-quarter normal size is the limit. The minimum space required for comfortable riding for a full-grown person with overcoat and wraps is 20 in. or 60 in. for three persons. Three three-quarter persons require  $3 \times 20 \text{ in.} \times .75 = 45 \text{ in.}$  or 2.25 persons, and this is the maximum width of rear seat inside it is possible to get. Now three  $\frac{3}{4}$  persons can ride comfortably on the rear seat as they are nicely wedged in and don't slide about, and in cold weather when bodily contact is not objectionable, are the only ones that can ride comfortably on the rear seat. It is most uncomfortable

for one or two persons as they slide all about and no way is provided to hold themselves against the sway of the car in rounding curves, turning corners and in passing other vehicles and the result is that the rear seat, which the owner uses and pays for is the least desirable seat in the car.

(7) The fact is, that the rear seat can never become a comfortable seat for one, two or three persons until the seats are individual and the back conforms to the body to hold it for side sway and it is also fitted with a fixed or folding arm to separate the two parties and so give them the ease of riding of an easy chair.

The easiest riding seat in the whole car is the divided or separated front or driver's seat, provided the width of the body is sufficient to allow a suitable width of seat after allowing for a 7 or 8-in. passage between the front seats. The incline of the foot board helps to make this seat easier riding than the rear seat, as the feet rest in a natural position and one can brace oneself. When foot rests are provided for the rear seats they should be of soft material and similarly inclined and adjustable or made wide to accommodate the different size passengers.

(8) Usually these separate front seats are made in part uncomfortable by having no supporting arm and back on the inner side, especially in many sedans, and so giving no lateral support to the body. You are compelled to grab the side of the car or slide off into the space between the two seats. Every sedan the writer has ever seen or ridden in has this defect, although most cars with touring bodies and separate seats are much better.

(9) This is probably due to the fact that the front sedan seats are made more or less separate from the body and the width of body itself is not sufficient. Taking the overall width of the front seats at 20 in. you have 20 in. plus 20 in. plus 8 in. or 48 in., which is impossible for the inside width of body and you have either to narrow the seats or passage or both.

(10) **Folding Seats.** The folding seats on nearly all cars could be greatly improved and the only ones at all practical are those having arms that fold also. The narrow flat disappearing seats may be pretty to look at when folded, but are of no use for continuous or long rides. When a purchaser pays \$4000 to \$10,000 for a car he expects to have every person ride in comfort, and further, he only buys a six or seven-seater because he expects to utilize the extra seats, and it is rather surprising to see what some of the makers have the temerity to offer.

(11) **Seating Arrangement.** The seating arrangement of all closed cars, limousines, sedans, etc., would be greatly improved if all seats were separate and could be revolved and fixed in any desired position, as they would be much easier for long rides and the individual could adjust the seat to his own convenience, and this would be very restful and would be much more sociable. This would also apply in great measure to the touring car, as it is not essential that any one except the driver should have a fixed seat facing front and even this could

well be adjustable and quite distinct from the body. It would certainly simplify and cheapen the body construction to have the seats independent of the body and the seats would then interchange for all types of bodies whether touring, sedan, close coupled, coupe, coupellette, etc. If these seats were mounted on tubular pedestal the entire inside of the car would have a clear open space to carry loose packages and parcels and be much easier to clean. Further, all of these seats might be adjustable for height to suit the different individuals.

(12) **Depth and Incline of Seats.** The depth and incline of seats required for comfort for the individual vary with the height of the seat; whereas, if these are adjustable both a fixed incline and any depth of seat can be used, but now oftentimes these seats are very uncomfortable.

(13) **Cushions and Upholstery.** The present cushions and upholstery are very heavy, clumsy, dirty and uncomfortable and would be much improved by using pneumatic cushions and backs, which might be separately attached to the body and easily removable. They would be much easier and softer riding, cheaper to make, lighter and more sanitary. Where you now have a 6 to 12-in. depth of cushion and back you would require only 4 to 6 in., or even less on the back, which would make a considerable saving in space required. As regards comfort in riding, there would be no comparison as you would eliminate entirely the vibrations of the car, especially if a pneumatic foot rest cushion were used.

(14) **Carrying Extra Tires and Detachable Wheels.** The most unsightly and disfiguring thing about the automobile is the carrying of the spare tires and the detachable wheels, exposed and in the dust and dirt. All close coupled cars and single seaters now have a rear projecting housing sufficient in size to carry one or two tires or wheels within the housing and free from dust and dirt and this would greatly improve the appearance of the car. All types of bodies could very easily be provided with a similar arrangement and in addition to carrying the two wheels or tires would have space around them available for carrying tools, dress suit cases, etc., and give a space that would be accessible at all times without having to disturb any of the passengers. The present arrangement of carrying pump, jack, tools, etc., outside or under the seats and disturbing the passengers in case of puncture of tire or any other mishap is quite objectionable.

(15) **Width of Body.** Whatever the width of the body may be or the width of the tread, the body should be free of the mud guards and these should always be attached to the chassis and form a part of the complete chassis, the same as the front mud guards. Any type of body can then be mounted on the chassis free from all attachments and any type of standard body interchange on a standard chassis. This would simplify and cheapen both the body and the chassis construction.

(16) The body construction is more or less delicate and can never be designed to carry the weight and vibrations of the mud guards in a satisfactory manner, and moreover, in the event of a slight collision, is apt to seriously damage the expensive body and add much more to repair cost.

(17) **Standard Width of Tread.** Where does Mr. Ferguson get his standard width of tread of 56½ in.? The S. A. E. standard is 56 in., which presumably comes from the old carriage tread. This country has 56-in. tread here in the north, although in the south 60 in. is standard and formerly much complaint was made because automobile makers were forced to make a 60-in. tread for the southern market. Undoubtedly many of the diffi-

culties of body design pointed out by Mr. Ferguson would have been overcome by adopting a 60-in. tread, especially where wide bodies are used and which as Mr. Ferguson points out, is done on practically all cars, whether large or small.

(18) The most fallacious of all standards is the adoption of a standard tread. We spend hundreds of millions a year in making smooth, hard roads and after years of experiment have only now succeeded in making a concrete or cement road that will not rut, and yet the engineers' mind conceives the existence of ruts, and as Mr. Ferguson points out, must design the car to run in these preconceived ruts, and which can only become realities by adopting the absolutely fallacious standard tread whose only function is to create the undesirable rut which the road maker must remove by repair or building an entirely new road.

(19) Instead of a standard width of tread what is wanted is a law that no two cars may be constructed having the same tread but rather as many widths of tread as possible.

What would be more logical would be to have the width of tread vary with the wheel base and the greater the wheel base (and presumably the larger the car) the greater the width of tread.

(20) If the widths of tread varied from, say 48 to 72 in., we would in great measure, if not entirely, eliminate any tendency of even soft or dirt roads to rut, and the different treads would tend to smooth out the roads.

If car treads, say, varied from 48 to 63 in. and trucks from 63 to 72 in., this would be accomplished. Practically now the larger trucks do have this variation of tread and do not produce ruts and except only that all cars have a standard 56-in. tread there would be no tendency to form ruts, and this is the very reason why the width of tread should vary with the length of wheel base and might well be a percentage of the wheel base.

(21) Assuming the width of tread as not less than 48 to 50 per cent of the wheelbase this would work out as follows: Wheelbase 100 in., 110 in., 120 in., 130 in., 140 in., 150 in. Width of tread 48 in. to 50 in., 52.8 in. to 55 in., 57.6 in. to 60 in., 62.2 in. to 65 in., 65.2 in. to 70 in., 70 in. to 75 in.

(22) The great advantage of a variation in tread would be most apparent on a soft or dirt road, for even if a hole or rut were temporarily formed the other following treads would "knead" it out more or less smooth again rather than increasing the depth.

(23) **Fixing Body to Chassis.** The fastening of the body to the frame should also be greatly improved and it should be so fixed that it may be easily and quickly removed and if necessary changed from a touring to a sedan, limousine or other type of body and arrangement made for lifting the body off and suspending it when the other body is substituted. Different conditions and times make it highly desirable and necessary to have either an open or closed or other type of body.

(24) The three-point type of suspension of body would also be highly desirable so as to protect the body from all the warping and bendings of the frame, and if this is done the body can be much more lightly constructed, besides being cheaper to make. The frame cannot be made that will not warp and it is absurd to try and prevent this by bracing the body to it.

(25) **Squeaks and Rattles.** Probably many of the squeaks referred to by Mr. Anglada are spring shackles, pins and leaves of springs and will always exist as long as the springs are exposed to dirt and dust and not properly enclosed and lubricated. The way to overcome the exposure would be to enclose them in a hollow frame, which can be easily and cheaply done, and then all these

can be continuously fed by oil and thoroughly lubricated, and would be entirely out of sight and add greatly to the appearance and simplicity of the entire machine.

(26) **Riding Qualities of Cars.** The riding qualities of all cars should be greatly improved and the amount of vertical motion of the body greatly reduced or eliminated. Any form of suspension that allows the body to deflect downward 4 in. more or less and rebound 8 in. when the wheels fall into a hole 1 in. must be eliminated and the body prevented from surging and vibrating back and forth for an indefinite period until it finally comes to rest and this initial deflection and rebound of flat metal springs can never be effectively prevented by shock absorbers. What is wanted is to absorb the shock instantly and "damp" out the vibration.

(27) This could be accomplished by the pneumatic tire itself on an absolutely smooth road (as smooth as the surface of the railroad rail) provided the air pressure was low enough, say 20 lb., but this is impractical as even if the tires would stand up the pressure is too low for safe steering of the car. On any smooth cement road, when the springs are not in motion the riding is satisfactory.

(28) To "damp" out greater shocks or vibration a secondary and lighter air pressure is required to suspend the body and frame pneumatically, just as the springs now suspend them, and this can be accomplished by an oval-shaped tire of standard section (but without built-up tread), completely surrounding the axle; at 20 lb. pressure. This will allow sufficient motion to the body and instantly check it and prevent all vibration.

(29) This pneumatic suspension would be much lighter and cheaper than the springs, shackles, pins, etc., and eliminate at least 100 parts. Triple pneumatic suspension could be obtained by using pneumatic air cushions with a still lighter air pressure 10 lb., utilizing, say, 60-20 and 10 lb. and giving an ease of riding and comfort that is not obtainable with any other method of suspension.

(30) These pneumatic frame suspension tires would also take up all horizontal road shocks and pneumatically cushion and absorb them, as well as dispense with all torque and radius rods and give a simple and ideal Hotchkiss form of drive.

(31) **External Brakes.** The most surprising thing about American cars is that, with a single exception, all are fitted with external contracting brakes, which are universally recognized as about the worst possible construction. It simply shows that force of habit beats competition and common sense and good engineering every time. Fortunately none of the designers of trucks have ever been guilty, but have invariably used internal expanding brakes arranged side by side and how any engineer or designer, especially of the more expensive car has ever had the temerity to continue to offer external brakes is beyond comprehension. The lives of the occupants depend on the brakes and it would seem that these require as much protection as 5 tons of coal.

(32) The external brakes are always covered with mud and dirt and all pins, etc., quickly wear out, as well as the soft braking material used. They are always out of adjustment and are loose or dragging 75 per cent of the time. It is bad enough to use soft braking material on an inside brake, but to use it on an outside brake is almost a crime. Imagine a railroad engineer substituting a soft-braking material for the metal to metal car brakes, and yet the railroad brake runs under relatively good conditions.

(33) There should be no more difficulty in arranging internal brakes side by side in a touring car than in a truck. Excessively wide brakes are not required, as it is

easy to make the drums of large diameter and again the brakes need not completely encircle the drum, but can be arranged to overlap or pass by each other.

If the adoption of four-wheel brakes would eliminate the external brake it would be the best thing that ever happened to the American car.

(34) **Pedals.** The pedals should normally stand flush with the incline of the foot board and should be the form and shape of the foot or like an organ pedal and when declutched or braked should depress below the fixed floor board and which, if necessary, should have a depressed lip or edge around the pedals. The foot is then always in a normal and easy position on the pedal and is instantly ready to slightly extend to declutch or brake without any lateral movement of the foot and will operate in one-fifth the time required when the foot is not on the pedal as at present.

(35) **Foot accelerator.** The present arrangement of the foot accelerator is very dangerous, for if the foot slips off the pedal and strikes the acceleration it opens the throttle wide and makes the car jump ahead and may cause a serious accident. It would be better if the action of the accelerator was reversed then it would stop the car. Pushing the other pedals stops the car and this should apply to the accelerator as well.

(36) In the form of pedal suggested above, the accelerator could be arranged within the right pedal so the foot would always be upon it, and by slightly elevating the front of the foot the throttle valve would be opened and when returned to normal position the throttle closed to any degree desired, and when the accelerator and right pedal was further depressed the accelerator could be arranged to pass into a neutral zone and not completely shut the throttle or further affect it.

W. J. P. MOORE.

## Improved Engine Cooling

Editor, AUTOMOTIVE INDUSTRIES:

S. D. Heron, in the "Forum" in the July 7 issue, does not specifically mention the comments that I made on "Water and Air Cooling" in the Engineering Number. However, I have the good fortune to be very well acquainted with the views of G. J. Mead, and believe that we are in fairly close agreement.

I believe that almost every engineer has a feeling that direct air cooling is logical, particularly for aviation. A few years ago there was a general belief, amounting to much more than a mere feeling, that air cooling would rapidly become universal for aviation. Probably the development of air cooling for motors was to some extent hampered by the war, because the water cooled engine was easier to build for the simple reason that more was known about it.

I believe that Mr. Mead and Mr. Pierce in their papers did not intend to do much more than compare the best air cooled engines of the present day with the best water cooled engines. In my brief article I tried to point out that while air cooling was admittedly going to be improved, there was also considerable scope for the improvement of water cooling.

The case seems to be analagous to that of the two-stroke cycle. Theoretically the two-stroke cycle has many advantages. Practically, twenty years and more of experimenting have not sufficed to make the two-stroke competitive with the more complicated four-stroke engine.

No open-minded engineer would ever say he believed the two-stroke engine would never be perfected. It can be regarded as one of those problems which is intensely stimulating but exceedingly difficult of solution. It is doubtful whether either air cooling or the two-stroke engine are

waiting for any great invention. To bring them to practical commercial perfection calls for a lot of petty experiments rather than for the discovery of new systems.

Cooling as an automotive engineering problem has been given extremely little attention by comparison with the labor which has been lavished on other details of the automobile and airplane. I expect to see both water cooling and direct air cooling steadily improve. Improvement in one will stimulate improvement in the other system. Mr. Heron very rightly says that "enthusiasm is a primary necessity for success in most mechanical fields of investigation." The enthusiasm which seems most desirable is the enthusiasm for *improved cooling*. If this be the ideal, then it can be worked out either in terms of direct air cooling or in terms of water cooling, or a possibility which is very seldom considered but quite alluring—a combination of both systems. There are just a few among us who can remember De Dion's tricycles of 1900 with air cooled cylinders having water cooled heads and valve chambers. These carried a very small quantity of water but they cooled wonderfully well.

A. LUDLOW CLAYDEN,  
United States Cartridge Co.

## Possibilities of the Air-Cooled Aircraft Engine

Editor, AUTOMOTIVE INDUSTRIES:

I have read the article by Mr. Heron in the "Forum" of the July 7 issue of AUTOMOTIVE INDUSTRIES, in defense of the air-cooled aircraft engine, in response to the paper by Mr. Pierce and myself, read at the S. A. E. summer meeting.

It seems that Mr. Heron's principal criticism was that we had overlooked the fact that much better air-cooled engines could be built. Unfortunately, he did not, apparently, understand one of the premises of the paper; namely, that it was dealing with the actual performance of existing engines. I entirely agree with Mr. Heron that there is a possibility for considerable development of this type of engine. I will, however, take up the points in the order they were discussed in Mr. Heron's article, with the hope that our ideas on the subject of the air-cooled type of engine may be more clearly set forth.

(1) **Parasitic Resistance.**—The statements in regard to the parasitic resistance were based upon a mathematical consideration of a large radial of 375 hp. and approximately 50 in. in diameter. The values derived were stated in Table 1, as compared with those of a water-cooled, V-type engine of similar power. The conclusion drawn from the figures was that a ship with the air-cooled engine would have a loss in high speed of some 5 per cent compared with the same ship with a water-cooled engine. As Mr. Heron says, there are no figures from actual performance available, at least not to our knowledge. It seems reasonable to suppose, however, that an engine with such a large frontal area would require additional power for its propulsion through the air at a speed corresponding to that of another engine of equal power with less frontal area in the same ship.

Smaller radial engines, by that I mean smaller in diameter, 40 in. or under, will not be subject to this criticism, since they fair into the fuselage very nicely.

(2) **Vulnerability.**—Our information on this subject and Mr. Heron's seem to differ somewhat. The consensus of opinion of some of the pilots who were on the western front seemed to be that more planes came down because of being set on fire than because of injury being done to their cooling systems.

(3) **Mean Effective Pressure.**—Our paper stated that

relatively low mean effective pressures had been secured so far in this country, which was correct at that time, I believe, and did not discuss the probable mean effective pressures that could be secured. The mean effective pressure of 120 lb. mentioned by Mr. Heron was only very recently secured with a single experimental cylinder, I understand.

(4) **Temperature Control.**—It is a more difficult problem mechanically to control the temperature of an air-cooled engine than of a water-cooled engine, which, I believe, will be granted. Whether or not it is necessary to carefully provide temperature control has yet to be proven.

(5) **Weight.**—Attention was drawn to the fact that, so far, air-cooled engines weigh very nearly the same, per horsepower, as the best water-cooled engines, complete with water and radiator. Mr. Heron himself makes the statement that successful air-cooled cylinders have proved to be fairly heavy. For that reason it is necessary to increase the mean effective pressure in order to make these engines capable of competing with water-cooled engines in the 400-hp. class.

In conclusion, the whole radial air-cooled situation, as I see it, is as follows:

Whether or not large radial air-cooled engines are to supplant or compete with water-cooled engines depends first upon developing cylinder constructions, which will permit of high mean effective pressures, and also to develop the mechanical parts of the engine so that they will be sufficiently durable for the service expected of them. I see no reason why air-cooled cylinders will not be developed which will give high mean effective pressures. Naturally, there is a great deal of careful experimental work to be done before the maximum efficiency of this type of cylinder can be obtained. Mr. Heron himself is doing some very conscientious work on this problem and undoubtedly in the near future will be able to tell us of the cylinder limitations. In the meantime, development work must be carried on with the mechanical parts of the engine, including the crankcase, crankshaft, connecting rods and valve gear, since in this type of engine the designer is seriously limited by the inherent compactness of the type in securing the proper strength and accessibility, as well as durability, of its various parts. With the cylinder and crankcase assembly satisfactorily developed, we will be ready to determine the advantages of this type in flight, which will involve testing its ability to work under various conditions of temperature, the powers available at various altitudes and the advantages in maneuverability due to the compactness. There is a great deal to this whole problem, and I am glad to say that it is being attacked with enthusiasm both by the Air Service and by individual engine designers in this country.

GEORGE J. MEAD, Chief Engineer,  
Wright Aeronautical Corporation.

THE Customs officers in Flanders have, it is announced, recently captured one of the very latest type of armored motor car in use among the smugglers on the Franco-Belgian frontier. It is a large truck, the front part being protected with heavy sheets of steel. In front of the radiator is a contrivance which looks rather like a snow plough, but which is, in fact, a steel bar intended to cut through obstacles placed across the road. The Customs officers who captured the vehicle only took it after a hot fight, in which firearms were freely used. More than 7000 packets of tobacco were found in the lorry, vehicle and cargo representing a total value of 45,000 francs.

# Increasing Individual Efficiency Through Decentralized Responsibility

Accuracy of information is not an end in itself. The information must result in time saving or waste elimination in proportion to the cost of getting the accuracy. As individual responsibility increases, the need for system decreases in proportion.

By Harry Tipper

**I**N the building up of the centralized systems of operation in industry to-day we are in danger of forgetting that the object of industry is to produce a salable article in accordance with the requirements of the market and to sell that product at a profit.

It is desirable to standardize operations, because by this method of standardization and repetition the products can be made more cheaply and in a much greater quantity in a given time.

It is desirable that the records involving the cost of the operations, the materials required in the operations and all the elements entering into cost shall be determined, with sufficient accuracy to facilitate the reduction of waste and improve the productive capacity.

Some of my friends in industrial pursuits have shown me the accuracy of their systems and have dilated upon and emphasized the accuracy as though the whole aim and end of a system was to produce accurate information.

Unless the accuracy of the information permits of saving in time and motion in proportion to the cost of discovering the accuracy, it is not worth while and it may result in a burden upon the business for which there is no concomitant return.

The human error cannot be entirely eliminated. It is not reduced by accurate information, but the information will enable the intelligent man to see where the error might be reduced and to take such steps as are necessary to secure its reduction.

Departments in industry that are concerned with the keeping of records regarding materials, the movement of materials, the cost of operation, the inspection of materials and the fabricated product, time studies and other matters, have a tendency to lose sight of the main object of the factory and to believe that the justification of their own work arises from the accuracy of a record and not from the usefulness of the information itself.

It is quite possible, and, indeed, is not unusual, for a slightly increased degree of accuracy to cost a great deal more money in record keeping, just as it does in shop operations.

Production men know well that a decrease in the tolerance allowance when it gets into the minute fractions increases the cost of the operations very materially and is not to be considered unless its importance is established and its usefulness thoroughly justifies the additional expense.

Similarly, in the records which are kept of the various factors which enter into operating wastes and costs, a certain degree of minuteness will cost so much more to determine that it is not worth while unless the usefulness of the information is very well established and its importance in the operating calculations justifies the additional cost of securing it.

All systems of this character tend to grow faster than the business with which they are connected and tend toward an increased cost in their operation beyond that which was originally or reasonably contemplated.

The same things have been discovered in systems of office practice many times.

A friend of mine who was very much enamored with the creed of accuracy in his advertising work had a most wonderful system for following up the inquiries received so that accurate information would be secured as to what happened to them, what they were worth, and so forth, until they could be considered as dead or completely sold. Products sold by his company entered into a number of industries and were used for a variety of purposes, so that the volume of inquiries was considerable. It required a very large force of people to follow these up and see that accurate records were kept of all the intermediate information and the final information.

One day somebody inquired as to the value of all this work, how much it actually forwarded the sale of the articles to those inquiring and to what extent it was justified by its effect upon the sales conditions. The result of that examination was the elimination of about two-thirds of it as unnecessary and not justified by the extra usefulness involved in its calculations. Apparently very little was done with it when it was secured, and the cost of getting it was very high.

The advantage of system is to increase the usefulness and the advantage of accurate information is to determine the wastes and to indicate the prospects of further use. Beyond this there is no special advantage of carrying into extreme detail the records, except in the research laboratory, where minutiae is of great importance.

The constant reference of all matters to the systematic development of information and records has a tendency to increase the slavish following of rule and precedent which is responsible for the lack of efficient judgment conspicuous in much of the business operation of to-day.

In one of the plants where they make automobile bodies and have a very large run of one type for one concern, one of the operations in the finishing line is the riveting of a particular piece in a certain part of the body. This operation had been performed for a long time on this particular type of body by a worker whose sole job it was to handle this rivet. In the course of time the manufacturer changed the design of this body somewhat, putting the rivet one inch farther up. For weeks the man on the job automatically reached to the old place, and it cost more for the adjustment of his errors than the work of riveting.

Because he had been on the job, considerable patience

was exercised in the attempt to get him started along the new lines, but finally the foreman solved the problem by making a board one inch high and getting the worker to stand on it. The man's judgment, his capacity for adaptation and his whole mental and physical skill had become so specialized in one direction and so atrophied in other directions that he could not accommodate himself to this slight difference in this operation even in a number of days.

There are many men who are engaged upon the work of keeping records, systems, etc., for factories who are just as incapable of thinking outside of their line of work as this man. Their judgment is lost, as far as its flexibility is concerned, and beyond the rules and precedents governing the matter they are without any means of adapting themselves or their work to any slight change in the conditions.

From the examination of many industrial establishments in the last few years and a consideration of the supervisory costs, methods and systems, I am rapidly coming to the opinion that we are over-systematized in most industries; that we have almost forgotten the reason for system, and the systems themselves have reached the point where a good many of their detail developments are no longer useful and may be detrimental to the process of production.

Personally, I think it would be an excellent thing to check the value of the systems by finding out what the foreman and the workman think of it as far as it affects their department. The man who does not run a machine, the man who does not handle the material and is not responsible for getting the work out is not likely to be able to distinguish the essential features of a system of records or operations from the unessential features. With him every precedent is as important as every other precedent and every rule as important as every other rule.

The old-time foreman frequently kept his records of material on pieces of paper stabbed on a file and his drawings of his shop plan of work were not accurate drawings. Nevertheless he was a good foreman, a better man in his day than many foremen at present. Almost always he knew what things were and where they were. His method of cost keeping was not so accurate, but his knowledge of costs was pretty thorough.

It may be necessary for us to decentralize our systems, give the foreman the tools of the system, make him responsible for the working out of these things in his own department in order to grow efficient foremen and to keep the systems down where they are 90 per cent useful and not merely 90 per cent accurate.

## Unemployment Statistics

THE status of the unemployment problem in some of the European countries is digested in a recent issue of *Labour Overseas*, a British government publication. The proportion of unemployed to the total population in some of the chief countries on January 1 was as follows:

Germany	15.0%
Belgium	9.6%
Norway	8.8%
Denmark	2.3%
United States	2.2%
Netherlands	1.5%
Switzerland	1.1%
Sweden	0.6%
Czechoslovakia	0.4%
Italy	0.3%

While the figures for France and England are not con-

tained in the digest, so that a percentage could be figured, the following statement is made: "In France there is serious unemployment in the textile and metal trades; at Paris 100,000 persons were said to be totally unemployed in November and at Marseilles 30,000 in January. Unemployment has also affected the British Dominions and Japan to an extent which is at least greater than is usual in normal years."

The situation in England itself is known to be very serious at the present time.

In reading the above percentages it should be remembered that the percentage of unemployed to the total population is given and that only one in five can be counted as a constant wage earner. Had the percentages been figured on this basis they would have been much greater, of course.

## Metal Coatings as Rust Preventives

EXTENSIVE experiments with zinc coatings are reported on by Dr. W. Lange in the *Zeitschrift für Metallkunde* for April. Four processes are dealt with, namely, electro-plating, dipping, sherardizing and spraying (Schoop process), which were investigated during the war at the instance of the army research department. Tests were made on small plates of wrought iron measuring 1.2 x 1.8 x 0.16 in. These plates, protected by the different processes, were subjected to the influences of distilled water, hydrant water, and a one-half per cent salt solution, as well as to the influence of the weather, partly in a humid atmosphere containing much carbonic acid gas.

After commenting interestingly on the different processes, the author reaches the conclusion that rust protection is approximately the same for all processes, if they are properly applied. Unsatisfactory results can practically always be traced to too thin a coating of zinc. One pound of zinc should cover from 200 to 380 sq. ft. When well applied, a coating of zinc gives protection against atmospheric influences and hydrant water for a considerable

period. But the protection against a one-half per cent salt solution lasts for only a short time. It follows that protection against sea water is also quite ineffective. The method of zincing best suited to any particular object depends on the form, cross section and the surface formation. For hardened and hard drawn objects, such as springs, steel wires, etc., plating, spraying and possibly sherardizing at low temperature may be used; for strongly profiled objects, objects with deep hollows, and steel pipes, dipping and sherardizing are recommended; for objects made to measure whose limits must be retained, plating and possibly sherardizing; for material on which further work must be done, like sheet metal, plating and dipping; for parts with seams and rivets which are to be made tight at the same time, dipping and spraying; for cast iron objects, spraying.

The life of the different coatings can be greatly increased if the zinc is covered with a coating of resinous lacquer or water glass as a protection against atmospheric influences.

## Tractor a Lusty Youngster

NINETY firms manufactured 203,207 tractors, worth \$193,563,000, in 1920. Of these tractors, 162,988 were sold in this country, at a value of \$161,896,000, and 29,143, valued at \$30,850,000, were exported. This is quite a remarkable showing for an industry which really dates its activity from 1914. Prior to that year the development of tractors was almost entirely along the line of large machines, which reached their peak of production in 1912, when 11,444 tractors were manufactured. The next year the number was fewer. The tractor had a small sale because it was available only for large farms. In 1913 the Bull tractor, the small farm pioneer, was brought out and this tractor sold in considerable numbers in 1914. Since then the development has been rapid.

It is worth mentioning that the value of the tractors manufactured is a considerable part of the farm equipment business, as the total for this industry, as given by the Department of Agriculture, is \$536,945,000. During 1920 only fifteen firms are reported as manufacturing steam traction engines and these

firms turned out only 1766 engines, worth only \$4,661,000.

Reliable figures of production and sale since 1916 are available through the United States Department of Agriculture, as follows:

	1916	1917	1918	1919	1920
Manufactured .....	26,670	62,472	132,697	164,590	203,207
Sold in U. S. ....	27,819	49,504	96,470	136,162	162,988
Sold for export.....		14,854	36,361	19,893	29,143
On hand Dec. 31.....		15,525	15,401	27,740	16,076

## The Vacation Problem

A NEW name for a somewhat old practice is seen in the announcements of factory shutdowns this year. In former years factories have been closed for certain periods "for repairs" and for "inventory" and for other reasons. This year some factories are closing for a week or more "on account of efficiency vacation."

The factories that are doing this are plants which give to their employees a vacation under pay. Previously it has been the custom to permit the employees to arrange vacation schedules that permit the more or less efficient operation of the plant. But this year several firms are announcing that the entire plant, including office, will be closed for one week, with the exception of a small force to answer emergency mail and to make emergency shipments. After the plant has been closed for the vacation period, everybody will come back refreshed and get to work again. One Brooklyn plant, which pays employees for two weeks' vacation period, has caused half of this vacation to be taken by closing the factory on Saturday mornings and the other half is taken through a full week shutdown.

## Profiting by Unsuccessful Experiments

HOW many engineers, even those with long experience and records of exceptional achievement, have had so-called "bright ideas" which when put to practical test have failed to materialize because of some unforeseen or seemingly insurmountable obstacle? Every engineer can recite experiences of this kind, many of them accompanied by long periods of what may seem to be fruitless research or development work. The experience gained by learning what is not desirable or attainable is, nevertheless, instructive and correspondingly valuable. Furthermore, it frequently happens that the information gained is or would be, if made available, of great value to other investigators, either in serving as a foundation upon which to build further or in showing what is not possible or commercially feasible. Again, two heads are often better than one. What may seem an insurmountable obstacle to one engineer may be circumvented or eliminated as a result of the experience of another.

For these and other reasons it would be a fine thing if engineers would regard it as one of their duties to report the results of investigations which they have occasion to make, whether directly profitable or otherwise. This is done in an unsystematic way in some

instances, especially when the investigation has proved a highly profitable one, but the idea might well be carried further. The Society of Automotive Engineers and other engineering organizations have accumulated much useful data in their transactions, but these represent but a small fraction of the useful engineering information that can and should be brought together.

We understand that the S. A. E. Research Department has in mind collecting and indexing all published material bearing upon automotive engineering. It might well go further and solicit from its members and others data of equal or perhaps greater importance accumulated through research efforts the results of which have never been published but which are filed away where they serve no useful purpose.

## Talk to Your Congressmen

**A**PPARENTLY the Republican majority in Congress is subject to pressure from those who placed the legislators in their present positions. This is indicated by some changes that have been made in the Tariff Bill and by the heed the Senate gave to the President's message on the soldier bonus.

This is as it should be, provided the proper persons speak the sentiment which reaches the legislators. So far it seems that much of the influence has been for good, but the legislator is never quite safe on a business program. Already the legislators have put oil on the free list, which is quite pleasing to the automotive industry, but it might be well to encourage them to keep oil where it now is. It might be possible for a change to be made in the aluminum duty if proper representations were made to the legislators.

Most of all, however, the automotive industry is interested in the carrying out of the Republican promises of a business administration, the lessening of taxes and similar movements. It will pay manufacturers to demonstrate that it is better politics to legislate for business than directly for political support.

## Car Resistance Factors

**I**N the S. A. E. paper by Mr. James, read at the summer meeting, the various resistances encountered by a road vehicle were enumerated, and constants were given by which each could be evaluated. In the case of air resistance a number of authorities were quoted, which differed considerably among each other, and it was pointed out that the highest constants were probably somewhat too high and the lowest too low.

It is doubtful whether any experiments have ever been made directly on an automobile to determine the air resistance at different speeds and to calculate therefrom the proper air resistance constant. S. F. Edge once determined with a car having a windshield the maximum speeds of which the car was capable with different windshield areas. However, as the projected area of the car without windshield, the power curve of the engine, the gear reduction and wheel diameter were not given, it was impossible to make use of the results in determining the air resistance constant.

That the constant found for flat surfaces moved straight against the air is not directly applicable to automobiles is obvious, because streamlining has quite an important influence on the air resistance, and the modern automobile body is to quite an extent streamlined. The constant for an average car body should, therefore, be smaller than the constant for a plane surface. On the other hand, there is a power loss in automobiles running at high speeds which is usually not taken into consideration and which undoubtedly varies with the speed in about the same way as the air resistance loss; namely, that due to road shocks and resultant slippage of the wheels on the road. When going at racing speeds, the driving wheels are out of contact with the road a considerable portion of the time, spinning around idly, and when they strike the road again the tires usually slip more or less until the pressure between tire and road has become nearly normal. That this action is the cause of great power loss is obvious from the experience of every driver that it is almost impossible to make any great speed on rough roads.

If this loss of power, which increases with the speed much faster than the tractive resistance loss and probably in about the same proportion as the air resistance loss, be added to the latter, then the highest values which have been given for the air resistance constant would undoubtedly be nearly correct. It is realized, of course, that the loss spoken of does not depend directly upon the exposed area of the car, but upon the total weight and the ratio of unsprung to total weight; but inasmuch as the shape of car bodies tends to become standardized, there is a fairly definite relation between exposed area and total weight.

## Educating Dealers

**I**T is interesting to hear factory sales managers discuss the necessity of educating the dealer and then to follow the way in which this education is carried out. It is easy to write "enthusiasm" material and it is easy for the dealer to react favorably to such material when times are good, but the general reaction during depression times is likely to be extremely unfavorable.

In either good or bad times, greater progress is likely to be made by fact-education. Not that inspiration is not an essential of good salesmanship. But an analysis of automotive selling indicates that there has been an excess of inspiration and a lack of merchandising analysis. Cars and trucks must be sold in the future on a basis of sound marketing studies. Every party concerned must do his part in gathering and correlating data. True dealer education will concern itself with talking to the dealer along these lines. Excellent results can be obtained by creating a "fact atmosphere," by emphasizing the necessity for study and analysis along selling lines. Automotive merchandising has never been short of enthusiasm and inspiration and those desirable qualities will not be lost if emphasis is removed from them temporarily. Several companies which have already started work in merchandising analysis are already profiting by the results of their efforts.

# Sharp Criticism for British Makers

## Increasing Imports Deplored at Meeting

### Combination of Standard Makes for Export Advocated at Heated Conference

By Cable to AUTOMOTIVE INDUSTRIES  
LONDON, July 25.—The conference here of British automobile manufacturers with British motor car dealers throughout the world resulted in sharp criticism of the shortcomings of British makers and their products from the viewpoint of overseas users.

Government spokesman deplored the increasing imports revealed in the striking trade returns, and advocated a combination of the standard British cars to go after business in overseas markets.

A spokesman for the manufacturers contended that while wages remain at the present levels, British makers cannot hope to compete successfully for foreign trade.

Dealers from all parts of the world told some homely truths which resulted in a proposal to hold a meeting under the auspices of the Board of Trade to discuss requirements for cars for export, probably on American lines.

Overseas critics averred that American cars are better than British, and asserted that claims of superior quality for the price in British makes were not well founded.

A spokesman for India resisted heatedly the claim that British vehicles give a greater mileage per gallon of gasoline than American cars.

The general impression is that the conference failed of its purpose, chiefly because of lack of adequate publicity. Editor Goddard of *Motor Export*, a monthly publication, who recently toured the British overseas market, asked the traders present for information concerning the needs in these markets and declared that British makers are slack in their publicity methods.

### STATE TO FIGHT OIL PRICES

BUFFALO, July 25.—The district attorney of Erie county has declared he proposes to take retaliatory action against the Standard Oil Co. which he accuses of "maintaining a high price for gasoline in the face of declining prices for crude oil."

## NATION'S PRODUCTION 87% OF 1920 IN 2ND QUARTER

NEW YORK, July 25.—Production of passenger cars by the automobile manufacturers which are members of the National Automobile Chamber of Commerce for the second quarter of 1921 was 57 per cent of the production by the same companies for the second quarter of 1920.

Ford production for the second quarter this year was 137 per cent of the same quarter last year.

Production for the industry as a whole in the second quarter of 1921 was 87 per cent of 1920.

Production by the N. A. C. C. companies for April, May and June was 107 per cent greater than for January, February and March.

Production by truck companies which are members of the N. A. C. C. for the second quarter this year was 39 per cent of the second quarter of 1920. It was 34 per cent greater than for the first quarter this year.

## Tire Exports Greater, Akron Makers Report

AKRON, July 26.—Akron tire manufacturers report heavier export business so far this year than at any time in the history of the tire industry. The volume of export business has practically doubled since the first of the present year. As indicative of the steady return to stable economic conditions in Europe, tire manufacturers report European export business increasing rapidly.

Mexico and South America continue to lag in export of tires, largely due to the fact that merchants in these countries have refused to write off their losses and are holding for war time prices, according to export managers of the "Big Four" of Akron, the Goodyear, Goodrich, Firestone and Miller Companies.

Goodrich recently has organized a separate or subsidiary export corporation and has established offices in Akron. Firestone this week has transferred its export departments from New York to Akron so that export managers can keep better in touch with the home office and can handle export orders directly out of Akron. This transfer brings G. T. Currier, F. C. Allen, W. H. Snyder and G. L. Livingston to Akron from the Firestone export office in New York, with L. A. Latour remaining in charge of the Firestone warehouses in New York City.

## Tire Exports Nearly Doubled in England

### Otherwise Shrinking Market Brighter by Cutting Down of Rubber Import Value.

LONDON, July 15 (By Mail)—The best that can be said of Britain's automotive trade returns—export and import for June—is that the end of the month marked the near cessation of the protracted period of British labor troubles. The cloud seems completely to have lifted with the decisive vote of the engineering unions—comprising some 30 and more affiliated bodies—in favor of accepting the wage reduction proposed and discussed between the masters and men some weeks before.

As to imports, during the month 602 cars and trucks and 391 chassis were imported, the combined value (at pre-war exchange rates) being \$1,344,360. The value of parts imported was \$626,620 and of tires imported \$1,144,005.

British vehicles exported numbered 166 and chassis 43, the combined values being \$938,740 and the value of exported parts was \$484,645 and of tires \$555,315.

The six months' totals were: Imports, vehicles and chassis, 6,619 as compared with 25,521 in the corresponding period of 1920; parts (value) 9,020,390, and tires (value) \$7,783,585 as compared with \$18,410,645 and \$12,582,440 in the like period of 1920.

British exports for the six months—Vehicles and chassis, 2,340 compared with 2,533 in the like period of 1920; parts (value) \$3,888,830 against \$4,244,615 in the like period of 1920, and tires \$16,088,030 against \$5,990,170 in 1920.

It will be noticed that while there has been a notable shrinkage of imports and exports generally during the six months, the export value of British tires has nearly doubled and the import value of tires has been nearly cut in half.

The interesting point here is that imported tires are duty free, yet the British tire trade is constantly urging that they should be taxed on the plea that British interests suffer and British workers would benefit by increased production following (it is hoped) the fall off in imported tires.

### ELGIN MAKES RECORD

ARGO, ILL., July 25.—The Elgin Motor Car Corp. has informed its dealers that the number of cars shipped for the month of June was 102 per cent larger than for any other one month in the past seven. Orders June 1 were 259 per cent greater in the same period.

# Rickenbacker Turns Manufacturer

## American Flying Ace Plans \$5,000,000 Firm

Backed by Walter Flanders and  
B. F. Everit—Files Charter  
Application

DETROIT, July 26—Capt. E. V. Rickenbacker, America's ace of aces, is about to enter the ranks of American motor car manufacturers, backed by Walter Flanders and B. F. Everit. Application was filed at Lansing yesterday for a charter for the Rickenbacker Motor Co., a \$5,000,000 concern backed by a group of automobile men which is of unusual strength and resource.

This is not the first time that Flanders and Everit have been associated as they were two members of the old E.M.F. group which later became the Studebaker Corp. The other name was that of William E. Metzger, who was the "M" in the combination. This organization looms large in the history of automobile manufacturing activity as one of the first to manufacture a low priced car in large quantities.

Since the sale of the E.M.F. concern to Wall Street interests, Everit has confined his attention entirely to his original business of automobile body building and he is to-day the second largest body builder in the world.

The name of Flanders is familiar to everyone in the automotive industry. He took over the defunct United Motors Co. from which he created the Maxwell Motor Co., of which he was head from 1911 to 1920. During that time this organization earned \$18,000,000 in profits, having started from what was known as a pile of scrap. Flanders has continued to insist up to this time that he was going to remain in retirement and in fact made this announcement in Detroit not more than ten days ago. Those well informed in the industry always have believed, however, that Flanders would come back.

Rickenbacker stated to-day that the design of his car was started over two years ago when he returned from Europe determined to enter the automobile manufacturing business. He states that the design incorporates many points learned through his own long experience in the automobile field and that of his associates.

As it now stands the organization includes Everit as president and general manager, Rickenbacker as vice-president and sales director, Harry L. Cunningham as secretary and treasurer. The other directors are Flanders, Carl Tuchenor, Roy Hood and E. R. Evans.

Cunningham is one of the closest men  
(Continued on page 193)

## COMPETITION SO GREAT TRAINS GIVE WAY TO MOTOR CAR

NEW YORK, July 26—An effect of automobile travel on railroad operation is shown in the decision of the Interstate Commerce Commission authorizing the abandonment of two branch lines of the Boston & Maine Railroad in New Hampshire. One, extending from Cherry Mountain to Jefferson in Cross County, a distance of three and one-half miles, was built in 1892 for the accommodation of summer resort travel. The increase in motor car travel has caused a steady diminution in the passenger traffic, and in 1919 and 1920 the company reported that the average number of passengers per train was three with total freight revenues in 1920 amounting to \$88 and total passenger revenues \$319.

The other branch line extending from Bethlehem Junction to Profile House, in Grafton County, a distance of nine miles, also had to give way to the competition of automobiles, as the report shows that the average number of passengers per train during 1920 was two, with revenues amounting to \$1,713 and operating expenses \$12,940.

## Hope for Reciprocal Duties on Implements

CHICAGO, July 25—Although the tariff bill passed by the House has placed imports of Canadian farm implements on the free list, hope is entertained that the Senate will place manufacturers of farm operating equipment in the United States on an equal footing with their competitors in the Dominion, which has an almost prohibitive tariff on farm machinery.

Some manufacturers believe that the tariff bill empowers the President to impose reciprocal duties. Because of the uncertainty which prevails, manufacturers connected with the National Implement and Vehicle Association have authorized their national legislation committee to give full consideration to the tariff question, with power to file a protest if American farm machinery manufacturers are not fully protected.

The section of the bill which relates to agricultural implements does not specifically mention tractors, and inquiry will be made to ascertain whether it is the intention to include them in list of farm machinery to be admitted free.

## Sherman Will Direct A.E.A. Sales Campaign

Executive Editor of Class Journal  
Co. Resigns to Conduct \$40,000  
Promotion Plan

NEW YORK, July 26—Ray W. Sherman, executive editor of the Class Journal Co., has resigned to become merchandising director of the Automotive Equipment Association.

Mr. Sherman will take up his new work Aug. 1, organizing and directing the sales promotion movement authorized at the recent Mackinac Island convention of the A. E. A. His headquarters will be in Chicago, where he will work with the sales promotion committee headed by Robert A. Stranahan, president of the association.

Before becoming executive editor of the Class Journal papers, Mr. Sherman was editor of *Motor World*, which he joined more than nine years ago. Previously he had spent several years in daily newspaper work and for a time was in the advertising department of the Franklin Automobile Co. He was graduated from Syracuse University in 1907.

The work which Mr. Sherman will undertake, with a staff of assistants, is virtually an educational campaign intended to carry a practical message of better merchandising to all branches of the automotive equipment trade. It will call for the co-operation of manufacturers, jobbers and dealers in plans yet to be worked out in detail.

## Manufacturers Study Enclosed Car Market

DETROIT, July 25—Automobile manufacturers are beginning to scan the horizon in a study of prospects for enclosed car business in the fall. It is too early to determine definitely the size of the probable demand in September, October and November, and dealers are not inclined to commit themselves.

It is felt among some well posted men in the industry that due to the reluctance of closed body manufacturers to make large commitments for materials there is a possibility of something resembling an enclosed car shortage during the fall. It is felt that when the vacation season is over a larger proportion of the cars sold will be of the enclosed type. It is certain that none of the body manufacturers are over-producing at this time on closed jobs. Manufacturers of cars say they will not be able to formulate plans for production of enclosed models until after Aug. 1, when they will have had a chance to sound out dealers.

## Atlanta Territory Sees Trade Revival

July Sales, However, Not Expected to Reach Those of June

ATLANTA, Ga., July 26—In spite of the price reductions effective July 1 and the resultant increase in sales that has been experienced by these various companies during the present month, as a whole July will not be as good a month for the automotive industry in the Atlanta district as June. The outlook for the future, however, is brighter than it has been for a number of months and indications are that automotive sales in this district will have picked up to an appreciable degree by the early part of fall.

A prominent Atlanta banker declares that a thorough investigation conducted recently by his bank leads him to believe that the situation is now on the road to rapid improvement.

"For some time economic authorities have been watching for the trend of affairs that will indicate a revival in business conditions," this banker declared, "and they are now beginning to see its advent."

One of the primary difficulties in the South is the continued and unexpected low price of cotton, which leaves the farmer without ample finances for the purchase of automobiles and almost closes this market entirely as a profitable one for the dealers.

Conditions as a whole, however, appear to be on the upward trend, and virtually all lines of business in this section appear to be noting favorable effects as a result.

## Headlight Law in Ohio Takes Effect August 16

COLUMBUS, July 26—The law enacted at the last session of the Ohio General Assembly regulating the glare of headlights becomes effective Aug. 16, which is the time of the expiration of the referendum period. The new law provides that no headlights can be used on the highways and streets of the state unless covered by a lens approved by the Ohio Highway Commissioner. No certificate of approval of lens can be issued until actual tests have been made by that official.

The provisions are that a light shall be used to disclose any persons, vehicle or object for a distance of 200 ft. ahead of the car, and no dazzling rays shall be used more than 3 1/4 ft. above the surface and not more than 75 ft. ahead of the car. No lamp shall be more than 32 candlepower. No spot light can be used except when projecting its rays directly on the ground at a distance of 50 ft. in front of the vehicle and to the right of the center of the roadway. Heavy fines are provided for violation of the provisions of this law.

## DIXIE DEALERS OPPOSE PROPOSED GEORGIA GAS TAX

ATLANTA, GA., July 26—The plan to raise upwards of \$3,500,000 per year in the State of Georgia by a special tax on gasoline and soft drinks, and which is now being considered by the State Legislature, will be bitterly opposed by the dealers according to present indications.

The tax on gasoline proposed is 1 per cent per gallon, and this would net the State additional revenue of \$800,000. The tax would, of course, be passed on to the ultimate consumer, but with the country still paying war taxes on most of its luxuries, various dealer organizations are planning to oppose the passage of the measure as an unnecessary hardship.

## Savannah Sales Good; Outlook Is Favorable

SAVANNAH, July 26—Savannah retail automobile dealers have experienced a decided improvement in business during the last two months as compared with the first three or four months of the year. June sales and general automobile business showed material increases, as compared with the preceding months, as a result of the reduction in prices, and a slight improvement in general business conditions, in this territory.

However, says Percy S. Bacon, president of the local dealers' association, the June sales are hardly better than the average monthly sales of last year. The first four months of this year were exceedingly bad for the dealers of this territory, but the recent improvement has given the dealers new hopes, and they are putting forth every effort to push sales forward.

Bacon explained that for the past two years the automobile business in Savannah has been greatly handicapped by the construction of concrete roads being in progress, which made long, boggy detours necessary. Since the completion of road and bridge work through this section, forming a direct route from the East, through Savannah and Brunswick into the State of Florida, the local dealers are expecting considerable improvement in business.

Depression in the cotton, naval stores and lumber markets, upon which Savannah and vicinity chiefly depend, has caused tight money and other factors which still prevail to considerable extent. Until these markets recover considerably, normal conditions can hardly be hoped for in this territory. However, reductions in prices by retailers in general have stimulated buying by local consumers considerably, and there is a tendency toward improvement in exports within the next six or twelve months.

The outlook for the automobile business in this territory is very favorable.

## July Sales in Texas Show 20% Increase

Dallas, Ft. Worth, Sherman and Waco Report Substantial Gains Over June

DALLAS, TEX., July 26—Conditions in the automotive industry in Texas continue to show improvements from month to month. As the June sales on the part of the retailers showed an increase over those of May so are the July sales showing an increase over those of June. A canvass of a score of retail automobile establishments in Dallas and a dozen in Fort Worth, Sherman, Greenville, Waco and other towns developed the fact that the sales for the first half of July show an increase of from fifteen to twenty per cent over the sales of the same period for the preceding month. Dallas wholesale dealers who are supplying retailers in north Texas, parts of New Mexico, Oklahoma and Louisiana report that sales are increasing over the territory.

The increase in sales of automobiles, according to the local dealers, is due to three things.

First—The marketing of the grain crops in this section of Texas is putting some \$30,000,000 in the pockets of the farmers. This money is getting into circulation and cars are being bought. The fruit and vegetable crop is being marketed and this is bringing some \$20,000,000 more to the farmers of this section. Money is freer, hence cars are being bought.

Second—The reduction in the prices of automobiles. Dealers who have made price reductions, and practically all of them have, say there has been a noticeable increase in sales since the reductions.

Third—It is the touring season and the roads are alive with motorists. More people are using automobiles for vacationing this year than ever before.

## Dealers Not Big Losers in Closed Chicago Bank

CHICAGO, July 26—The best information available shows that Chicago automobile dealers who were depositors in the closed Michigan Avenue Trust Co. will not be heavy losers, as their accounts in most cases were small and represented balances carried to meet payrolls. As a consequence motor row is not much concerned.

The Chicago Clearing House committee has issued a statement advising the public that the closing of the bank has no bearing upon general banking conditions, which are sound. Auditors now at work expect to have a statement ready in a few days. The troubles of the bank date back to a deal with the Graff Mfg. Co., which obtained a loan of \$250,000 on the strength of a contract with the Packard Motor Car Co. of New York which later was canceled.

## Indianapolis Hopes to Beat July Figures

### Cole Orders Show 45 Per Cent Gain Over Period of Pre-Reduction

INDIANAPOLIS, July 26—As July nears an end, it is evident here that the volume in business will exceed that done in June by a larger per cent than was expected. The greatest increase can be noticed by those automobile companies who have just recently made cuts in prices. The increase at the Cole plant has been noticeable. Since the reduction in prices, orders received at the plant show an increase over the pre-reduction period of approximately 45 per cent. Other plants are able to show increases of from 20 to 30 per cent. Those companies which made reductions earlier in the year are having a steady business, tending, officials say, toward a slight increase. These companies obtained increases immediately after prices were cut and contrary to all predictions here their sales did not slump after the first increase.

Dealers in automobile accessories here appear to be more optimistic concerning business for July and for the remainder of the year than the strictly motor car dealers. In accessories for smaller cars, such as the Dodge and Ford, the shock absorbers head the list. Dealers say that the demand for bumpers, special wheels, spot lights and locks has been good, better in fact than was expected.

Latest bank reports show business in the banks to have increased materially during the past six months of 1921 and savings accounts to have shown more than their proportionate share of increased business. In spite of this fact, Indianapolis bankers are more cautious than usual in lending money.

Automobile finance organizations, which finance the purchaser in a payment plan, appear to have plenty of money at the present time and report that since June 15 much better credit conditions have prevailed. Many accounts which have been past due for weeks have been paid up and payments now are being made regularly. The percentage of non-payment is less than it was this time a year ago.

### Turn in Kelly Tire Stock

HARTFORD, CONN., July 25—At a meeting of persons interested in the fate of the Kelly Tire & Rubber Co., Benedict M. Holden explained the status of the company. It was pointed out that the stockholders would be lucky if they got 50 cents on the dollar.

Nathan E. Prince, vice-president of the Hartford-Connecticut Trust Co., has consented to serve on the stockholders' protective committee. This is composed of bankers in New Haven, Waterbury and Hartford. Plans are now being considered as to the best means of protecting the interests of the investors.

## DETROIT PLANTS PUT 22,976 MEN TO WORK SINCE MARCH

DETROIT, July 26—Virtually the entire increase in employment in Detroit since March has been in the vehicle and transport group of manufactures. In this industry, which includes the automobile factories, employment increased from 53,205 in February and 81,093 in March to 104,069 in June.

## Restrictions of Banks Affect Sydney Sales

SYDNEY, AUSTRALIA, June 14 (By Mail)—The vast majority of would-be purchasers of motor cars in New South Wales are prevented from buying owing to the restrictions banks are now exercising with their clients who owe them money. The banks are pessimistic, but recently a few optimistic notes have been sounded by some bank managers in their annual reports to shareholders. The automobile trade has just finished up its summer business, which under such conditions has established the worst record since 1912, and as a result most of the motor car dealers are stocked with cars. There are a few fortunate ones who have cleaned up their stocks, but there are others who have heavy stocks and it will be twelve months before decent orders are placed for more cars by some of them. The purchasers are still waiting for prices to fall.

During the first two weeks in June the motor trade has been busy discussing the tariff with the Federal parliament of Australia, and it is predicted in some quarters that the import duty on the chassis will be reduced, but that the present duty on the complete car will be continued. An energetic campaign is being waged to get a lower duty on farm tractors and motor trucks. The duty on farm tractors has been considerably higher in proportion to that on automobiles than it should.

Wool, which is one of the staples of Australia, has for over a year come through a very bad period. As this is the biggest revenue producer in the country, this situation is naturally reflected in the buying power of the people.

For months it was impossible to sell a single pound of wool. There were no buyers and no offers. Lately the position has become slightly changed and indications point to a gradual improvement. If such develops it will bring about a decided improvement in business conditions throughout the Commonwealth of Australia.

In New South Wales motor truck business has shown improvement of late, whereas in the remainder of Australia it is practically dormant. Truck improvement in New South Wales is due to the heavy hilly nature of the populated areas.

## Car Demand Improves in Columbus Field

### Closed Plants Gradually Resum- ing—Records Show More Workers Are Employed

COLUMBUS, July 26—There is a continued improvement in the demand for passenger cars in Columbus and central Ohio territory. This is the report from dealers and distributors of cars in almost every line. With a number of price reductions announced during July, business in certain makes was still further stimulated. On the whole trade is much better than was expected.

There is a slight improvement in the unemployment situation which is shown by the reports of employment agencies and also from reports received from large employers of labor. Some of the plants that were closed down early in the year are gradually resuming and are employing more men from time to time. Other concerns are still holding their own, and as a result there are fewer men out of work now than was the case a month or six weeks ago. This is being reflected on the automobile trade, especially passenger cars. People are now inclined to take a chance, for it is the belief that the worst of the slump is over and that conditions are on the mend.

But dealers and distributors are not too optimistic and they are proceeding cautiously. The larger majority believe that the improvement will be gradual and they do not expect a boom during the present year. They are working on the principle that a certain number of cars will be sold with things brightening up, and it is up to the dealer to hustle for the business. Consequently, salesmen are being trained to pick up prospects and to handle the prospects after they are secured. It is a long, hard grind ahead of the sales force, and special efforts are being made to keep up as much as possible.

### May Modify Ford Offer

WASHINGTON, July 26—Secretary of War Weeks says that Henry Ford's offer for the Government nitrate plant at Muscle Shoals, Ala., is unsatisfactory in its present form. He said that in several respects the Ford proposal was not in the exact form expected, though he thought it likely that modification could be made in the offer when he discussed the proposal with Mr. Ford, which might make it acceptable. The date has been set for a conference between the two.

### A. M. E. A. Convenes Oct. 5

NEW YORK, July 26—The annual convention of the American Manufacturers Export Association, which numbers several automotive manufacturers among its membership, will be held at New York on Oct. 5 and 6, and various matters of importance will be discussed.

## Automobile Market Depressed in Japan

**Imports Close as Yokohama  
Sheds Fill Up with Cars  
and Trucks**

SEATTLE, WASH., July 26—Continuation of the depressed state of the automobile market in Japan has led to stoppage of automobile imports and to the accumulation of large numbers of cars and trucks in the customs sheds at Yokohama, according to the latest reports from the Orient. A partial recovery in retail sales was felt in the first four months of the year, but since then conditions have slumped somewhat and it is now felt that no marked improvement will come until autumn.

Retail dealers in Japan complain that would-be purchasers of automobiles feel that the prices asked for standard makes of cars are too high. The average American or English car sells for an amount in Japanese currency equal to twice the retail price in the country of manufacture. And yet conditions are such that even at this price the automobile dealer in Japan, it is said, can make but a small profit. Transportation and boxing costs add greatly to the cost of the foreign automobile, and the high import duty in Japan is charged not on the original cost of the automobile but on the original cost plus boxing and transportation charges. Transportation, boxing and insurance costs amount to from 15 to 20 per cent of the first cost of the automobile. To this cost must be added the landing charges, an item which has greatly increased in the last few years. Charges for interest on money tied up must also be added.

### Consider Own Production

In face of the present high cost of imported cars, home production of automobiles is again being talked of. Several attempts to manufacture Japanese automobiles have been made, and are being made at this time, but so far they have been generally unsuccessful. In one or two instances a small, light car of satisfactory performance has been produced, but the manufacturers have been unable to interest local capital in sufficient quantities, and as a result the production costs have been high, and the selling price has not been appreciably lower than asked for of foreign vehicles of similar size.

Japanese labor is not yet sufficiently skilled or sufficiently experienced to be suitable for use in automobile manufacturing. It is considered that Japan will not be able to produce her own cars and trucks for 15 or 20 years.

The recent passage of the new motor taxes in Tokyo have added to the motorist's burden. One Tokyo writer says that not only is Tokyo content with having the worst roads of any large city in the world, but that it has the double distinction of imposing the highest automobile taxes.

## COLE CAR BOUGHT BY KING CONSTANTINE OF GREECE

INDIANAPOLIS, July 26—The Cole Motor Car Co. obtained an order to-day from King Constantine of Greece for a Cole car, all decorated in a coat of arms, nickel-plated fixtures and everything. Before Greece got the king bug the last time, its ruler had a Cole car and while officials of the company do not know whether Constantine requisitioned the car after he resumed the throne, yet he has fallen in love with a Cole car to the extent of ordering one.

## Installing Budget System in Goodyear Tire Firm

AKRON, OHIO, July 26—President E. G. Wilmer, of the Goodyear Tire & Rubber Co., who recently succeeded F. A. Seiberling, has put into operation a complete budget system for the entire Goodyear factory and the main offices and all branch offices. The budget plan was adopted following a conference of Mr. Wilmer and other Akron officials, with New York banking interests now virtually in control of the Goodyear company through the \$80,000,000 refinancing program recently negotiated.

Under the system each factory or office department and every branch office has been assigned a specific budget, with the order issued to each departmental manager to hold his expenses within his respective budget for the ensuing year. Heretofore Goodyear has operated without a budget and without a financial board of strategy to pass upon expenditures, new expansions and addition of high salaried men.

## Preston Motors Starts Shipments to Europe

BIRMINGHAM, ALA., July 26—Shipments to foreign countries by the Preston Motors Corporation have recently begun according to an announcement by James T. Driver, vice-president and general manager of the corporation.

The first car sailed from New York on the steamer Woodrow Wilson for the distributor of the Premocar in Yugoslavia last Saturday. While only one car was shipped the agency has ordered three carloads more, and they will sail as soon as possible.

Applications for a distributor's franchise have been received from Africa, Australia, England, Germany and many other foreign nations. Just as soon as the production warrants this territory will be closed. The Creel Motor Company, local distributors, have dotted the state with Premocars. A departure from the general rule is shown in the fact that the Premocar is just as popular at home as it is elsewhere.

## Cleveland Dealers Predict Good Gains

**July Will Be from 25 to 30%  
Better Than Average, They  
Assert**

CLEVELAND, July 26—Basing their estimates on the volume of business done the first two weeks of July, representative Cleveland dealers assert the present month will be from 25 to 30 per cent better than the average July in the past.

Reductions in prices brought an influx of new business that has continued through the middle of the present month in this city. Many owners and others wanting to own a car this year kept holding off for lower prices, until now dealers say the demand indicates that the average man and woman is of the opinion that the last price reductions on 1921 cars have been made.

The Chandler car is now selling at the pre-war price, and the local dealers say that June sales went up surprisingly, and that the first two weeks in July are far ahead, from the standpoint of new cars delivered, of the corresponding period in 1920. This statement is borne out by Samuel Regar, treasurer of the Chandler Motor Car Co. He said that retail sales of Chandler cars throughout the country for June were the largest of any month since October 1920.

The Jordan dealer, who says that his June sales were the best for any similar month in the history of his firm, asserts that July this year is likely to establish a new record.

Reports at the Dodge, Chevrolet, Willys-Knight, Overland, Studebaker, Auburn, Franklin, Hudson and Essex, Stutz and Buick agencies are that July this year is better than the average.

The automobile industry here seems to accurately reflect general business conditions, as portrayed by the Cleveland Trust Co. That bank says:

"Business cycles pass through four separate phases—prosperity, forced production, liquidation and readjustment back to better times. We are now in the third and fourth phases, and while liquidation is not entirely completed, readjustment is under way. When prices are falling the tendency is to get rid of stocks on hand. During this transition industry stagnates, unemployment is general and business is bad, because everybody wants to sell and few want to buy. Such a situation always corrects itself because consumption is greater than production and stocks become exhausted and have to be replenished. Evidence is accumulating that the rapid fall of wholesale prices has stopped.

### Stockholders Ask Receiver

EVANSVILLE, IND., July 25—A group of stockholders in the Stronghold Tire & Rubber Co. has filed a petition in the county court asking for a receiver. It is alleged the company is on the verge of bankruptcy.

## \$90,000,000 in Truck Contracts Hang Fire

**Russian Soviet Officials Who Made Them Under Arrest in Chicago**

CINCINNATI, July 26—A few days ago the United States Motor Truck Co. of Covington, Ky., had contracts for \$90,000,000 worth of automobile trucks for the Soviet government in Russia. To-day the company is wondering whether the contracts are good or not.

F. J. Alvin, an official of the company, also is wondering whether his appointment as Director of Standardized Motor Truck Equipment for the Russian government in the United States, also is valid.

The Trailmobile Co., the Highland Body Co., and other Cincinnati concerns interested in automobile building, also are wondering as a result of recent developments in Chicago.

Max Schallman, a representative of the Soviet government, made the contracts and promised Alvin the appointment several months ago. No money was passed at the time and the companies with which contracts were placed, including several not directly engaged in the automobile business, were waiting for the passage of the coin before undertaking the contracts. But the contracts, nevertheless, were all signed and ready, once the money was shown.

Schallman since has been arrested in Chicago on several charges by Federal authorities, in connection with his activities in this country. His attorney says he will carry the contracts as soon as delays, beyond his control, are overcome. These are due to affairs across the sea, it was said.

The firms concerned are up in the air and awaiting definite word on their contracts. Alvin's appointment was to supervise standardized truck manufacture in some 15 or 16 truck plants throughout the country, at which contracts were to be made by Schallman.

It is charged that the contracts were made to get business men interested in recognition of the Soviet government, because of the pressure they would bring to bear on congressmen and senators due to their contracts.

## New South Wales Plans \$243,000,000 Road Loan

NEW YORK, July 26—A loan of \$243,000,000 will be raised in New South Wales to carry out the reconstruction of the main roads throughout the State. This report to the Bureau of Foreign and Domestic Commerce states that the loan, which will carry 5½ per cent interest, is being arranged by the State treasurer. The scope of the main roads bill has been enlarged by extending its area throughout the county of Cumberland. Every penny of the huge loan, says the report, will be devoted to the building of good roads.

## CIVILIAN AVIATORS FLY 3,250,000 MILES IN SIX MONTHS

NEW YORK, July 26—The Manufacturers Aircraft Association, on completing an aviation survey of the United States, announced today that in the last six months the 1200 commercial planes in operation had flown approximately 3,250,000 miles.

"The record," says the survey, "shows that civilian flying, although embarrassed by the lack of an American air policy, has established itself as a remarkably safe and dependable means of transportation. In three and a quarter million miles of travel by air, only 15 persons were killed and 43 injured in a total of 27 serious accidents. Most of these accidents occurred among that class of civilian aviators known as gypsy flyers.

"Of the 1200 commercial aircraft, probably 1000 are under the indirect supervision of responsible plane manufacturers or transportation companies—and this is absolutely the only regulation over flying, as local ordinances or state laws cannot be enforced. Lacking a Federal organization controlling civilian aviation, these 200 or more gypsy flyers have been permitted to fly at will and many have met disaster."

## Stockholders Will Buy Immel Company Assets

COLUMBUS, July 26—The sale of the Immel Co. plant together with all materials and equipment at the other two plants of the company to Arthur G. Gilmour, chairman of the committee of stockholders, has been approved by the court. Steps are now being taken to organize an entirely new corporation to take over the property and operate it for the manufacture of closed automobile bodies, to which purpose the plant has been placed.

A meeting of the former stockholders who have participated in the sale will be called soon, when it is hoped to select a name and to iron out details for the incorporation of the company. All financial matters will also be considered at this meeting. It will probably be weeks before a definite announcement.

## Cut Kalamazoo Trucks

KALAMAZOO, MICH., July 26—A general price reduction ranging from \$300 on the lighter models to \$425 on the heavier trucks has been announced by the Kalamazoo Motors Corp., which manufactures the Kalamazoo truck. New prices f.o.b. Kalamazoo range from \$2,495 for the 3000-lb. truck to \$4,800 for the road builders' special 5-ton truck.

## British Labor Back; Industry Sees Hope

**Automotive Trade One of First to Benefit Big Return of Workers**

LONDON, July 10 (By Mail)—The tenseness of the British labor and general industrial situation has subsided more rapidly than it took to develop. The miners have resumed work, the engineers have come to terms and will continue at work pending further discussion, and the cotton operatives have resumed work. Thus the three chief British industries have again reverted to a reasonable course and the fact finds expression in the slogan, "Full speed ahead."

The factor underlying these disputes has been the problem of wage rate and the acceptance of economic necessity of a reduction of cost of production. On all hands the Government is blamed for lack of provision in handling the affair. It "controlled" industry just long enough to suit its purpose, and just as quickly decided to cut the control, with the result that labor and employers were thrown at each other's throats.

The automobile industry will be one of the first to benefit by the resumption of labor, and in a few days the stock of the automobile companies should begin to reflect a hopeful issue.

At present the demand is exclusively for light cars and motorcycles. Big stuff has slumped, so much so, that it is probable one of the big factories would suffice for all the salable output in that category.

## Companies to Increase Daily Tire Production

AKRON, OHIO, July 25—The Goodyear Tire & Rubber Co. is preparing to increase production to 25,000 tires and 30,000 tubes a day. Considerable difficulty is being experienced in obtaining skilled tire builders.

The Firestone Tire & Rubber Co. announces that its production will be raised 23,000 tires and 25,000 tubes a day. Substantial increases are reported in orders both from manufacturers and dealers.

NEW YORK, July 25—The Kelly-Springfield Tire Co. is producing in excess of 2300 tires a day at its Akron and Wooster, Ohio, plants, and 700 a day at the new Cumberland, Md., factory. Output at Cumberland is being increased as rapidly as possible. More than 900 men are employed there now, and the number is being increased each week. The production at this plant alone is expected to reach 5000 a day by the end of the year.

BOSTON, July 25—The Fisk Rubber Co. is increasing its production. The output now is running 8500 casings and 10,000 tubes daily.

## Cost Cuts Chief Help to Ford Meeting Loan

Sharp Manufacturing Reductions  
Aided Him to "Put It Over"  
on Bankers

DETROIT, July 25—Details of the manner in which Henry Ford overcame the financial difficulties which confronted him early in the year and escaped from the bankers who were waiting eagerly to get a share in his business by means of a loan, have been printed at length recently in the daily newspapers. The salient facts were recounted in *AUTOMOTIVE INDUSTRIES* some two months ago.

The most striking feature of the story is the sharp reduction made in manufacturing costs. All non-essential jobs were abolished. Late in 1920 the average cost of labor and commercial overhead per car, exclusive of material, was \$146. Now it has been cut to \$93. Formerly 15 men were required per day per car. Now it requires only nine.

Early in January Ford needed \$58,000,000 to pay \$33,000,000 in bank loans which he made to buy the holdings of the Dodge Brothers; \$18,000,000 for Federal taxes and \$7,000,000 for employees' bonus.

He had on hand \$20,000,000 in cash and raised \$24,700,000 by the sale of cars manufactured from parts on hand in the main factory and the assembling plants. He collected \$3,000,000 due on foreign accounts and realized \$7,900,000 by the sale of liberty bonds. Another \$3,700,000 came from the sale of coke and by-products. This left a margin of \$1,300,000 for operating expenses.

The additional funds needed were obtained by making use of the Detroit, Toledo & Ironton Railroad. Before he got control of the road it took an average of 22 days to haul raw materials to the factories, work it up, and get it to dealers. The money tied up in this way stood constantly at about \$88,000,000. This time was cut to 14 days and the amount tied up reduced to \$60,000,000. This left \$28,000,000 for operating capital.

## English Firm Acquires Willard Patent Rights

CLEVELAND, July 26—C. A. Vanderwell & Co., Ltd., of London has acquired the patent rights covering the manufacture of the Willard threaded rubber insulated battery for the United Kingdom and British dominions, excepting Canada, according to an announcement made today at the office of the Willard Storage Battery Co. The threaded rubber takes the place of the wooden fiber separators in the battery and makes the battery much more lasting.

The device is the invention of Willard and it has been used in this country for more than a year with such good results that the Vanderwell company sought the right to use it.

## SEIBERLING RETURNS TO THE RUBBER INDUSTRY

NEW CASTLE, PA., July 25—Frank A. Seiberling, former president of the Goodyear Tire & Rubber Co., has "come back" to the rubber industry, as his friends predicted he would, after relinquishing control of the huge corporation he built up from the humblest of beginnings.

Under a court decree he will take possession of the New Castle Rubber Co. which he purchased for \$103,000 at a bankruptcy sale some time ago. This price was considered very low, as the factory is well equipped and cost several times that amount.

While awaiting confirmation of the sale by the court, Seiberling told New Castle bankers that he expected to take personal charge and begin operation as soon as possible.

## Dealers Fight Georgia Accessory Tax Measure

ATLANTA, GA., July 26—Volney Williams, president of the Georgia Automotive Dealers Association, appearing before the House committee on appropriations and ways and means of the Georgia State Legislature, now in session, told members of the committee that the tax increases proposed by the present assembly on automobile and accessory classifications are too high, and that if the present taxes are increased to any appreciable degree it will have the effect of putting a large number of dealers in Georgia out of business within the next year.

A bill revising the general tax act in the State so as to produce an estimated increase of \$500,000 a year to the State revenue beginning Jan. 1, 1922, has already been introduced before the General Assembly. Wholesale and retail dealers in automobile tires and accessories are placed in separate classes in this bill, wholesalers being taxed \$250 a year and retailers \$25 a year. There are other proposed forms of taxation in the bill that will have a serious effect on the automobile industry in this State if it is passed. The bill providing for a tax of one cent per gallon on gasoline appears to be a certainty regardless of the efforts that have been made to defeat it.

John B. White a Bidder

SPOKANE, WASH., July 26—John B. White, president of the Washington Tire & Rubber Co., bid in the assets of the corporation when they were sold by the sheriff to satisfy a judgment given the Lincoln Trust Co. on a \$65,000 bond issue. He is understood to have been acting for himself and other stockholders.

## Trade Officials to Confer with Hoover

Conference to Discuss Compila-  
tion of Census of 1921 Pro-  
duction Figures

WASHINGTON, July 26—Representatives of the National Automobile Chamber of Commerce, Rubber Association of America, and other organizations in the automotive trade will attend a conference of trade associations with Secretary of Commerce Hoover and the officials of the Bureau of Census, next Friday. The conference will discuss the best methods by which the organization may co-operate in the compilation of the biennial census covering statistics of products of manufacturing industries taken for the year 1921.

John E. Edgerton of the National Association of Manufacturers has issued a notice to members of the association and to trade bodies which are co-operating in this activity.

The Director of the Census desires this conference with representatives of the associations in order that he may consult with them concerning the number, nature and form of the various inquiries and the general scope and work of the Census Bureau, as well as the methods of co-operation with the officials of the bureau and department to facilitate the work and accomplish the best and most useful results to American industry.

Among organizations asked to send representatives to the conference are the American Iron and Steel Institute; American Supply and Machinery Manufacturers' Association; National Association of Engine and Bolt Manufacturers; National Association of Brass Manufacturers; National Pipe and Supplies Association; Heating and Piping Contractor's National Association; and Railway Car Manufacturers' Association.

## Chicago Holding Own, Hopeful for Future

CHICAGO, July 25—With small losses in sales volume during the past ten days, as compared to the high spot for the month, business with the Chicago dealers is holding much better than was hoped. Sales during July have reached a high mark for the dull season and many dealers are of the opinion that August will produce business that will carry that month beyond its average volume. J. V. Lawrence, vice-president of the Henry Paulman Co., Pierce-Arrow distributors in Chicago territory, summing up the automobile situation said:

"Good business is going to continue up to about Sept. 15. About that time I look for an increase in sales to last for two months. I believe that we will sell more automobiles from Sept. 15 to Nov. 15 than we have ever sold before during the same period of the year. My judgment is that December will be dull."

# American Car Wins French Classic

## Duesenberg, Driven by Murphy, Shows Way to Europeans

De Palma Second in Thrilling Road Race—Flying Stones Force Two Out

### How They Finished in French Grand Prix

Driver	Car	Place	Time
Murphy	Duesenberg	1	4:07:11
DePalma	Ballot	2	4:22:10
Goux	Ballot	3	4:28:38
Dubonnet	Duesenberg	4	4:30:09
Boillot	Talbot-Darracq	5	4:35:47
Guyot	Duesenberg	6	4:43:13
Wagner	Ballot	7	4:48:01
Guinness	Talbot	8	5:06:43
Segrave	Talbot-Darracq	9	5:08:06

By cable to AUTOMOTIVE INDUSTRIES

PARIS, July 25.—Jimmy Murphy, an American driver, piloting an American-made Duesenberg car, carried the Stars and Stripes to victory to-day in the post-war renewal of the classic French Grand Prix for cars with a piston displacement of 183 cu. in. (3 litres). It was the first big European race in which an American team had taken part. The distance was 321.78 miles.

Ralph De Palma, veteran American pilot, finished second, fifteen minutes later, in a Ballot. He has flashed past the stands in the lead, lap after lap, on the Indianapolis speedway in the American classic, in the same French car, but not to victory.

The race was largely a duel between Duesenbergs and Ballots. Six of the nine cars which finished carried the hopes of these two makers. There were two Talbot-Darracqs and one Talbot. The Ballots took second, third and seventh places, and the Duesenbergs first, fourth and sixth. Boillot in a Talbot-Darracq finished fifth, and the Talbot-Darracq was ninth and a Talbot eighth.

The race, on the outskirts of Le Mans, 30 times around a fast triangular course measuring 10.7 miles, was hotly contested from the first lap to the last. In the early circuits Joe Boyer, in a Duesenberg, and Jean Chassagne, in a Ballot, furnished many of the thrills. Mechanical trouble put them out near the end.

JIMMY MURPHY

Jimmy Murphy, who won the French Grand Prix for America in a Duesenberg, is one of the latest American drivers to spring into fame. He is a product of the Pacific Coast and began his racing career as mechanic for Eddie O'Donnell and later with Eddie Rickenbacker. He drove a Duesenberg in the Indianapolis races this year and finished fourth.

Boyer and De Palma ran a dead heat for first place in the initial lap, with Chassagne and Murphy neck and neck in second place. The other leaders, in order, were Wagner, Guinness, Boillot, Guyot and Dubonnet. In the first lap Wagner had clutch and carburetor trouble.

Murphy and Boyer were in the lead in the second lap, followed by Chassagne and De Palma. On the third lap the two leaders were unchanged, but Chassagne went into third place ahead of De Palma.

The cars stood in this order until the end of the sixth lap, when Boyer stopped to look at his wheels and Chassagne went into second.

At the end of the seventh Murphy stopped to change tires and take on gas as a precaution, giving Chassagne the lead. The order up to that time was, Murphy, Chassagne, Boyer, Guyot and De Palma.

While Murphy was at the pits for gas and tires, Boyer raced into second place, but Murphy soon overtook him and pressed hard after Chassagne but the Ballot held the lead until the seventeenth lap. Then Chassagne went to the pits with his gas tank leaking badly from a puncture made by a flying stone. This accident forced him to leave the track and Murphy went into first place again

(Continued on page 197)

## N. A. C. C. in Split with Underwriters' Body

Severs Relations with Chicago Laboratories Over Question of Car Grouping

NEW YORK, July 27.—The National Automobile Chamber of Commerce has definitely severed relations with the Underwriters Laboratories at Chicago, an adjunct of the Underwriters Association. The last straw was the determination of the Laboratories to group cars according to mechanical construction.

The activities of the Underwriters Laboratories are regarded as too detailed. The inspections interfere with the routine of factory production and result in classifications which are illogical. Parts makers who do not submit to the laboratory tests do not get ratings and as a consequence a car may be unfairly listed because not all of its parts have been supervised, although they may be just as good or better than those inspected by the laboratories.

Few accidents to-day are due to faulty construction and automobile makers feel that nothing is gained by the tests in the Underwriters Laboratories. The high insurance rates are the result of over-valuation and failure to take into consideration the moral hazard. This virtually puts a premium on the destruction of motor vehicles.

## Rickenbacker Enters Manufacturers' Field

(Continued from page 187)

in the automobile industry and has been associated with Everit and Flanders practically since the beginning of the business. Cunningham helped Alexander Winton build his first car and was chief assistant to Henry Ford when he built the old "999." He had been Ford branch manager in Detroit and continued as consulting engineer until the E.M.F. organization was started when he joined this group. His last position was that of sales engineer in charge of production in the Maxwell-Chalmers Co. Since Flanders left Maxwell-Chalmers Cunningham has been devoting his entire attention to perfecting the Rickenbacker car.

Hood has had a similar history. He has been noted as a purchasing agent in the automobile field and started as assistant purchasing agent of the E.M.F. group. He later held the same position with the Studebaker Corp. and then became purchasing agent of the Maxwell-Chalmers. His position in the new concern will be that of purchasing agent.

## Willys Passes Peak of Output, Is Belief

**Orders for 5-Day Working Schedule Posted—August Production 6500**

TOLEDO, July 26—Willys-Overland has passed the peak of sales for the present season, it is believed by officials at the plant here, as orders were posted on Monday calling for five-day working schedule and lowering of production for next month.

The mark set for July was 12,000 cars. This has been cut to 10,500 cars, and August mark set at only 6500. The September schedule is 2750. These are only tentative, and if the trade continues as brisk as it has been during the last few weeks they will have to be revised upward.

The sales for the present week will probably temper the schedule for next month. Rarely has Overland operated extensively during the summer months.

Last week hundreds of men were laid off and during the next ten days the force will probably be cut by 2500 men. It is planned to keep a normal force of about 5000 men at work during the fall months.

President John N. Willys declared last week that the operations of the company had been so successful the last few weeks that financially it was now "out of the woods" and that it would go forward in fine shape.

He said that bank loans would be reduced on August 1 by a substantial payment in cash. The company's statement shows a cash balance on hand of approximately \$10,000,000, which will go far towards retiring the \$21,000,000 of loans. The loans were due in May but were extended until November.

It is thought by that time the plans of the creditors' committee will be ready and that a bond issue will be floated as a part of the clean-up for the loans and strengthening of the financial structure of the company.

## BOSTON 'SAFETY WEEK' WILL FOLLOW BIG CONVENTION

BOSTON, July 26—Motor accidents and how to prevent them will take a prominent part in the discussions of the annual convention of the National Safety Council, which this year will have its meeting at Boston. Governor Channing H. Cox has given the officials the use of the State House and there will be some 20 meetings every day in the committee rooms at the capitol, and also on Boston Common will be staged some interesting features relative to accidents. There will be meetings also in some of the other cities in the State. Plans will be worked out for a Safety Week in Boston in which everyone will be asked to take part.

## Automobile Men Buy Fletcher Bank Stock

INDIANAPOLIS, July 25—Five men prominent in automobile industrial circles of Indiana are in the group of stockholders which has acquired the interests of Stoughton A. Fletcher in the Fletcher American National Bank, leading financial institution of this State, according to announcement by the bank, made public to-day. They are Carl G. Fisher, president Indianapolis Motor Speedway and the Fisher Automobile Co.; James A. Allison, president Allison Engineering Co.; Walter Marmon, president Nordyke & Marmon Co.; Edward G. Sourbier, president Stutz Fire Engine Co.; Lucius M. Wainwright, president Diamond Chain & Mfg. Co.

"It is common knowledge that I have invested a large part of my personal worth in the Midwest Engine Co., which like many other large manufacturing concerns has had its share of troubles due to the present industrial depression," said Fletcher, in connection with the announcement of disposal of his holdings.

## Automobile Excise Tax to Be Retained

**Little Chance of Abolition—Federal License Fee May Also Be Added**

WASHINGTON, July 26—Outlook for elimination of excise taxes on automobiles is not particularly encouraging at this time when the House Committee on Ways and Means is framing a new revenue bill. The Treasury will recommend the abolition of the excess profits tax, reduction of transportation tax, reduction in surtaxes, elimination of so-called "nuisance" taxes and other minor changes. The President has been advised that the House will enact the tax bill by August 6, but House leaders say it will be fortunate if the bill is reported out of committee by August 15. Indications are that a Federal automobile license tax will be approved by the Ways and Means Committee.

The United States Chamber of Commerce advised the Ways and Means Committee that a canvass of business throughout the country showed that the second largest vote on taxation matters was for the repeal of the war excise taxes ranging from automobiles and their accessories to wearing apparel.

The sales tax which the National Automobile Chamber of Commerce had endorsed, has been definitely shelved by the House Committee on Ways and Means. As there will be no need for extra funds to meet a soldiers' bonus, the sales tax will not be necessary, though Congress must devise methods to raise \$4,000,000,000.

It is known that the Ways and Means Committee is likely to accept the program of tax revision, as submitted by the Treasury, because it affords the easiest way out of a difficult situation. The House Committee will undoubtedly amend the Treasury plans, but the belief exists that the recommendations of the Administration will be given as the views of the committee. The Senate Finance Committee conducted extended hearings on the sales tax last spring.

The Treasury believes it possible to enforce a Federal automobile license tax which would be paid directly by the consumer or the user.

## Rush Work on Verlinden Plant of Durant Motors

LANSING, MICH., July 25—Rapid progress on the Verlinden plant of the Durant Motors Corp. is being made. The Christman Construction Co., which has erected four cement towers for work, is now completing the second floor of the main plant and its various units. Steel for structural work on the warehouse and the enameling plant is on the ground and work on this is starting to-day. The Christman company is beyond schedule on the plant and from present outlook will turn over the plant on Nov. 1.

## New Durant Car and Nameplate

Durant Four, which will sell for \$890 and will be on market about Aug. 1, now on display in Long Island City

## 203,000 Gas Tractors Output for Last Year

### Department of Agriculture Makes Statistical Report on Farm Implements

WASHINGTON, July 26—Production statistics of farm implements as compiled by the Bureau of Public Roads, United States Department of Agriculture, show that there were 203,000 gas tractors manufactured during the year 1920, with a value of \$193,000,000. These figures represent the output of 90 firms and 162,988 tractors with a domestic sales value of \$161,896,000, while 29,143 were foreign sales valued at \$30,850,000.

The statistics regarding farm implements were compiled from reports of 583 manufacturers of tractors, farm vehicles and other operating equipment. It is believed that at least 99 per cent of the manufacturers answered the questionnaire sent out by the Department of Agriculture. The reports of a considerable number of firms covered the fiscal year ending in the latter part of 1920 or the early part of 1921.

The reports of such firms do not represent exactly their activities for the calendar year of 1920, but in every case the report covered an entire year, and it is believed that for all practical purposes the totals may be considered representative of the industry for the calendar year. The total value of implements manufactured was \$537,000,000. The export of tractors represents a large proportion of the total of foreign trade in farm implements, though there were 85 firms manufacturing horse-drawn vehicles. The total value of 449,095 vehicles was estimated at \$42,423,000, of which \$40,929,000 were domestic sales.

### New Buick "Four" Will Be Marketed for \$975

FLINT, MICH., July 27—The Buick Motor Co. announces the following prices on the various models of its new four-cylinder car: Touring, \$975; roadster, \$935; coupe, \$1,475; sedan, \$1,650. The engine is of the valve-in-head type, has a three bearing crankshaft and cylinder dimensions of 3 3/4 x 4 1/4 in. The oiling system is a combination of pressure and splash and the cooling water is circulated by a pump. The Marvel carbureter is standard equipment and it is provided with a new automatic heating system which is interconnected with the throttle so that the amount of heat supplied is dependent on the speed of the engine.

The clutch is of the multiple dry disk type. The front universal is incorporated with the gearset and lubricated from it. Hotchkiss type drive is used and the springs are semi-elliptic all around. The wheelbase is 109 inches. The body is finished in black with a white stripe on the touring model. The shipping weight is 2380 lbs.

### GAS PRICES SOARING, COMPANY INSTALLS OWN PLANT

NEW YORK, July 27—The Doehler Die Casting Co. of Brooklyn is installing a gas manufacturing plant of its own because of the high price it has to pay for its supply from gas companies. The Doehler company figures that it can make its own gas at a cost of 40 cents a thousand cubic feet. Its bill for gas last year was \$117,000.

The Doehler company was one of a number of manufacturing concerns which some time ago petitioned the Public Service Commission for a sliding scale of rates for industrial consumers of gas, the charge per cubic foot to be reduced as the volume of gas consumed was increased. No action has yet been taken, but the Doehler company doesn't intend to take any chances.

## Buyers' Strike Asked to Cut Tractor Price

### Georgia Commission Tells Farmers Manufacturers Must Reduce Farm Implement Charges

ATLANTA, GA., July 26—In a statement that has been widely published in Alabama newspapers, M. C. Allgood, Commissioner of Agriculture for that State, calls upon the farmers to declare a buyers' strike against tractors and other power farming machinery until the manufacturers reduce prices. Allgood, in his statement, declares that he is taking this matter up with other agricultural departments in the various southern states with the end in view of effecting an organization and bringing the subject to the attention of Congress for an investigation.

The statement declares that while agricultural products are bringing only a small fraction of the prices paid during the war, farm implements are now selling at 100 per cent more than the prices existing before the war began.

### General Motors, in Educational Booklet, Tells Stockholders Company's Magnitude

NEW YORK, July 25—The General Motors Corp. is mailing to stockholders with the Aug. 1 dividend checks, an educational booklet telling them something of the magnitude of the corporation. Few persons, even among the stock-

holders, have any definite idea of the wide ramifications of the great enterprise. The following table shows sales of passenger cars and commercial vehicles by divisions for the past four calendar years:

Years Ended Dec. 31	1920	1919	1918	1917
<b>Passenger cars:</b>				
Buick .....	111,215	115,405	74,856	117,300
Cadillac .....	19,826	19,801	12,279	19,692
Chevrolet .....	126,397	127,362	81,435	109,111
Oakland .....	36,155	51,901	24,110	33,951
Oldsmobile .....	25,713	33,345	18,822	22,045
Scripps-Booth .....	8,779	8,128	4,008	2,545
<b>Commercial cars:</b>				
Chevrolet trucks ...	13,651	6,098	384	2,664
GMC trucks .....	5,137	7,729	8,997	5,861
Oldsmobile trucks ..	8,239	7,782	30	15
<b>Totals:</b>				
Passenger cars ....	328,085	355,942	215,510	306,644
Commercial cars ...	27,027	21,609	9,411	8,540
Miscellaneous* .....	36,421	28,607	21,913	11,319
<b>Grand total:</b>				
Cars, trucks, tractors	391,533	406,158	246,834	324,503

\*Consists of tractors; McLaughlin, Chevrolet and Olds cars produced and sold in Canada, and therefore not included in reports to National Automobile Chamber of Commerce; and also Buick and Cadillac commercial cars.

The corporation has 78 divisions, subsidiaries and affiliated companies in 35 cities of the United States and Canada. These plants embrace more than 2000 acres of land upon which there are over 1500 buildings with a floor space of more than 32,000,000 sq. ft. The Buick plant at Flint, which covers 200 acres, is 1 1/2 miles long and 1/4 mile wide. The new Cadillac plant at Detroit covers 46 acres. The central office building in Detroit is the largest office building of its

kind in the world and contains 1,400,000 sq. ft. of floor space.

In addition to the manufacturing plants, the various divisions have large investments in factory branches, service stations and retail stores in all the principal cities of the United States and Canada. Chevrolet alone has 38 retail stores. Every city of importance in the world is covered by the General Motors Export Corp. and other foreign organizations of the corporation.

## Fail on Agreement on Motor Gas Range

Conferees Leave Matter to Results  
of Experimental Work Now  
in Progress

WASHINGTON, July 23—Inability of the conferees attending the meeting of the Technical Committee on Standardization of Petroleum Specifications to agree, left the determination of the new distillation range of motor gasoline to the results of experimental work now in progress. The suggestion that the present ninety degree point should be raised slightly was objected to on the ground that the specification should be retained unchanged until such time as an entirely new grade of gasoline can be used. The committee plans to study the specifications for aviation gasolines and for all grades of greases during the coming year and, therefore, did not set any specifications for these items.

The committee agreed that the acid heat test for gasoline and the cold test for steam cylinder and black oils were unnecessary, but the fire tests for lubricants should be continued in specifications as a check on sampling. It was decided that the new American Society for Testing Materials Methods should be adopted, though due consideration should be given the fact that these methods are still in a tentative stage. More definite color standards at a corrosion test for gasoline were also discussed.

Of interest to automobile manufacturers and owners was the belief expressed by the conferees that further definiteness would be desirable in the test for emulsifying properties of lubricants. It was shown that the words "light," "medium," etc., as applied to these oils have different meanings when these oils are used for different purposes, and a system of numbering was advocated to replace the present names for the grades. A slight broadening of the viscosity limits was suggested in order to allow several commercial grades of oil to qualify under the specifications, and a relaxing of the color and pour test standards was advocated for the same reasons.

The committee will study the suggestions submitted at the conference and recommend action by the technical committee and the interdepartmental committee.

## Chemical Fuel Is Cited by Federal Commission

WASHINGTON, July 25—The Federal Trade Commission has cited Chemical Fuel Company of America, Inc., Louisville, Ky., in complaint of unfair competition in the sale of a motor fuel in interstate commerce. Thirty days are given the company in which to file answer.

According to the complaint, this company sells a motor fuel known as tri-

oxalene, which, it is stated, is advertised as having been thoroughly tested by the United States Government Bureau of Mines, and has fulfilled every claim made for it as a fuel for all classes of aircraft, seaplanes, etc., and is the most perfect automobile fuel.

The complaint alleges that these representations are false and misleading in that no official test of tri-oxalene has been made by the Bureau of Mines, and that chemical engineers in that bureau who made unofficial tests of this product did not regard it as having any commercial merit or being of scientific interest.

This citation is made after a preliminary inquiry, and initiates a proceeding to try out the case on its merits, the hearings to commence on Aug. 31.

## Slow Production May Cancel Many Orders

PHILADELPHIA, July 26—A canvass of eight suburban boroughs and towns shows that while new automobiles are, in most instances, selling well, there is now danger of some of the sales being cancelled because of slowness in factory production. In not a few instances customers who have ordered cars and found they could not be delivered for many weeks, if not exceeding two months, have stated their intention, in case of non-delivery within a specified time, to cancel the order and obtain a car of another make whose factory is producing.

While the sale of accessories, with the exception of such articles as greases, windshield cleaners, and the like, is absolutely flat in most of the dealers' places as well as garages, tires are beginning to show more movement, except in far-outlying points. Trucks are slow and nothing much is being done in the line of trailers.

## Blame Gas Tanks for Coast 'Plane Crash

Should Not Have Been Carried  
at Base of Wings, Say  
Aviators

BERKELEY, CAL., July 26—Placing of the gasoline tanks at the junction of the wings with the fuselage is held by aviators of this part of the country to be responsible for the total destruction of the Jacuzzi monoplane, built in Berkeley, at Modesto, Cal., July 14, with the accompanying deaths of the four men who were riding in the plane.

Harold L. Coffee, of Oakland, former overseas aviator, was piloting the Jacuzzi monoplane when it fell. With Coffee were Giocondo Jacuzzi, brother of the inventor of the monoplane and chief financial backer of the Jacuzzi Monoplane Co. of Berkeley; A. Duncan McLeish, former army aviator and attorney for the monoplane manufacturing company, and John A. Kauke, service supervisor of the Cleveland Tractor Co., also of Berkeley. All were dead when spectators reached the fallen plane.

### Eyewitnesses Tell Story

The gasoline tanks were carried at the bases of the wings, and eye-witnesses of the accident say that the first sign of trouble was the explosion of one of these tanks, when the wing supporting it literally leaped from the side of the plane. A second later the other wing was seen to fall as the other gasoline tank exploded. The Jacuzzi company had been warned by local fliers prior to this flight that if either one or both of these tanks exploded both wings would be blown from the machine and the plane would be helpless in the air.

### Exports of Automobiles, Airplanes, Trucks, Farm Tractors, Motorcycles and Parts for June and Twelve Previous Months

	Month of June				Twelve Months Ending June

## Johnson Will Direct G. M. in Great Britain

Appointed Managing Director—  
Succeeds J. H. Willson—  
Raskob and Sloan Return

(By Cable to AUTOMOTIVE INDUSTRIES)

LONDON, July 23—Walter H. Johnson, managing director of Delco-Remy, Ltd., has been appointed managing director of General Motors, Ltd. and will have charge of the distribution of the entire General Motors line in England.

### Appointment Not a Surprise Here

NEW YORK, July 26—Appointment of Walter H. Johnson as managing director of the British subsidiary of the General Motors Corp. did not come as a complete surprise. He will succeed Joseph H. Willson, who retired from the service recently and who is now in the United States.

Johnson handled the Delco and Remy products in England before the organization of Delco-Remy, Ltd., something over a year ago and when that company was formed was placed at the head of it.

When the bottom dropped out of the market for automobiles in England, General Motors was heavily overstocked in all its lines as the possibilities of the market had been greatly overrated. Liquidation is now progressing rapidly, however, and the outlook is gratifying.

Johnson came to the United States on the Aquitania with J. J. Raskob, vice-president in charge of finances, and Alfred P. Sloan, Jr., vice-president in charge of operations, who had been abroad on business for about a month. They were accompanied by Christian Lie, manager of the Paris branch of the General Motors Export Corp.

Sloan and Raskob spent all their time in London and Paris where they made a careful analysis of industrial and business conditions. They were gratified at the recent turn of events in both England and France.

Lie, who gained fame in the Ford organization, is making his first visit to the United States in two years. He will remain here about two months. Johnson will stay in this country only a fortnight, studying the General Motors organization. Willson, who is succeeded by Johnson, was manager of the Chevrolet branches in Brooklyn and New York before he joined the General Motors Export Corp. as assistant sales manager.

## Murphy in Duesenberg Wins Grand Prix Race

(Continued from page 193)

in the twenty-second circuit. He held it until the finish but it was no easy victory.

In the 26th lap Guyot was running second and seemed likely to hold that position until the finish, but a stone, hurtling up from the road, intervened.

The missile hit his mechanic on the head and so nearly stunned him that when clutch trouble developed he could not crank the car.

This brought one of the dramatic incidents of the race. Arthur Duray, watching the contest as a spectator in the grandstand, realized what had happened, vaulted the fence and took his place beside Guyot as a mechanic.

The mishap dropped Guyot from second to sixth place, however, and gave DePalma, running with a leaky gas tank, the opportunity for which he had been hoping. The American veteran went into second place and never was headed.

Boyer went out on the 18th lap with a broken connecting rod, while trailing Murphy. The only other eliminations were Small in a Mathis and Thomas in a Talbot-Darracq, who was forced out two miles from home when a stone pierced his oil tank. Nearly all the drivers were cut by loose stones from the roadway.

The entire Sunbeam, Talbot and Talbot-Darracq teams were withdrawn a week before the race but 24 hours before the start two Talbots and two Darracqs were re-entered.

The Duesenbergs had a slight amount of tire trouble but the Ballots with the new Pirelli straight side cord had none. The Dunlop straight side cords used by the Talbot Darracq proved a failure and had to be changed during the race for Oldfields and Michelins.

The course was the shortest ever used in France for the Grand Prix and did not stand up to the speeds which can be made by modern cars. There were no accidents, however. Although the race was run under the auspices of the Automobile Club of France, the LeMans club played a prominent part in the arrangements and hopes to get permission from the Government to transform the road into a permanent speedway. It is not intended to close it to ordinary traffic but to provide permanent stands, pit, barricades and bridges. Half the course was a national highway, very wide and almost straight with a maximum grade of 3 per cent.

All the cars were equipped with 8-cylinder ahead engines except Goux's Ballot which had 4 cylinders of 2 litres piston displacement, and the Mathis which had a 4-cylinder motor of 1½ litres displacement. The smaller Ballot was entered, however, only because of the wrecking of the 8-cylinder used by Renard, who was killed in practice. It finished third and its success promises well for the 2-litre Indianapolis race in 1923.

The Ballots were on the same general lines as those entered at Indianapolis. DePalma drove the same machine he used in the American race except for a new engine.

The Talbot and Talbot-Darracqs were built along the same general lines after the design of Louis Coatalen.

The Duesenbergs differed in several respects from the European cars. They had no Hotchkiss drive, they had hydraulic brakes on all wheels, the total weight was lower and they had a left hand drive for a race run clock-wise.

## METAL MARKETS

UNNOTICED at first, because overshadowed by the financial highlights which featured the now famous Henry Ford interview, one of the Detroit passenger car builder's remarks is now coming in for considerable discussion by steel producers and buyers, because of its vital bearing on the market. Mr. Ford stressed the fact that the Ford Motor Co. was no longer buying its supplies months ahead, but from month to month. Producers argue that, if this method of steel buying were to become a permanent and general custom it would necessarily bring about enhanced costs. In the last few months steel mills have had to take orders of the hand-to-mouth buying sort, and were glad at that to get them. But buying of this sort amid the abnormal conditions of the last few months is one thing and a permanent doing away with contracts for a reasonable time ahead quite another. The entire structure of the steel industry is reared on a sufficient backlog of orders to enable mills to anticipate their own wants in the way of ore, coke, limestone and other raw materials. Mr. Ford himself placed an order the other day for 135,000 tons of iron ore for his River Rouge furnace; if he did not provide himself with the ore necessary to keep his furnace in blast in winter time, while lake navigation is open, he would have to pay rail transportation, thus adding considerably to the cost of every ton of iron. Non-integrated steel mills are no less compelled to anticipate their wants on the basis of contracts in sight, if they are to produce economically. Only a few days ago such sheet mills had opportunity to buy sheet bars at a considerable saving, but without any backlog of sheet orders on their books they naturally felt timid. Automotive purchasing agents, no less than steel producers, appear to be of the opinion that, once the steel market has settled down to a more dependable course than that which has been in vogue of late, there will be a return to the system of placing orders for reasonable tonnages a sufficient time ahead to warrant mills in operating on a dependably economic basis which will redound to the consumers' benefit. For the time being the market remains in a plastic condition, with much talk of further downward revision in "official" prices, but a steady increase in the volume of demand. While further announcements of price reductions are by no means precluded and may come over night, the market generally may first permit competition to reveal more clearly whether such cuts are necessary and what their extent should be.

Pig Iron.—Blast furnace interests are beginning to assume a more firm attitude and bids below the market have less chance of acceptance than heretofore.

Steel.—The Trumbull Steel Co., Warren, Ohio, is rolling a substantial order of strip steel for Ford Motor Co.'s account. The latter interest as well as other automotive manufacturers figure in extensive bolt and nut transactions in the Cleveland market. As a result, the market for nuts and bolts has turned firmer. In the sheet market, where there are numerous reports of price concessions, the situation seems to be that mills which can make immediate shipment usually obtain full or close to full prices, while on deferred shipments concessions of \$2 a ton and upward are more or less frequent. Demand for full finished automobile sheet is slightly lower.

Tin.—Cheapness of this metal has failed to bring about better demand.

**BANK CREDITS**

*Written exclusively for AUTOMOTIVE INDUSTRIES by the Guaranty Trust Co., second largest bank in America.*

The outstanding feature in the credit world last week was the reduction of rediscount rates by four of the Federal Reserve banks and similar action by the Bank of England. The announcement was made on Wednesday by the New York, Boston, Philadelphia and San Francisco banks that the new rate for all rediscounts and advances had been fixed at  $5\frac{1}{2}$  per cent to take effect on Thursday, July 21. This is the third reduction announced in the current year by the New York Federal Reserve Bank. This action reflects the improved credit situation and is evidence of the belief by the authorities in control of the Reserve Board's policy that money rates are not likely in the near future to show any sustained and decided firmness. On Thursday the Bank of England also announced a reduction of its rediscount rate to  $5\frac{1}{2}$  per cent, reflecting the improved credit situation in England.

The lower discount rates were made possible by the continued improvement in the reserve position of the Federal Reserve System. During the week gold reserves of the system increased \$15,554,000, and total discounts declined \$17,831,000 and Federal Reserve notes in circulation \$39,220,000. Federal Reserve notes in circulation, \$2,564,613,000, were at the lowest point since Aug., 1919. Total earning assets of the system declined \$35,392,000, while deposits declined less than \$1,000,000. As a result of these changes, the ratio of total reserves to deposit and Federal Reserve note liabilities combined increased from 61.6 per cent to 62.5 per cent, and the ratio of gold reserves to Federal Reserve notes in circulation, after setting aside 35 per cent against deposit liabilities, increased from 78.9 per cent to 80.6 per cent. The improvement was even more marked in the case of the New York Federal Reserve Bank, where the reserve ratio increased from 68.7 per cent to 70 per cent and the ratio of gold reserves to Federal Reserve notes in circulation, after setting aside 35 per cent against deposit liabilities, increased from 102.8 per cent to 105.9 per cent. Gold reserves of the New York Bank increased \$13,059,000, while Federal Reserve notes in circulation declined \$8,947,000 to the lowest point since July, 1918.

In spite of the advancing crop moving demands, there are distinct signs of easier money. This became really apparent in the local market following the announcement by the New York Federal Reserve Bank of the lowering of its rediscount rate. Call money ranged from 5 to 6 per cent as against a range of  $5\frac{1}{2}$  to  $6\frac{1}{2}$  the previous week. For the first three days of the past week a uniform rate of 6 per cent was quoted, but on Thursday, following the announcement of the rediscount cut,  $5\frac{1}{2}$  per cent became the renewal rate for the re-

mainder of the week. On the "outside" market,  $5\frac{1}{2}$  per cent money was said to be available at all times, and near the close of the week call funds could be obtained for  $4\frac{1}{2}$  per cent. Time money continued unchanged at 6 per cent to  $6\frac{1}{2}$  per cent for all maturities from sixty days to six months, until Thursday, when loans secured by mixed collateral declined to 6 per cent and "all-industrial" loans declined to  $6\frac{1}{2}$  per cent. Trades were few, however, and unimportant. Commercial rates were also affected by the easier trend in the money market. Sixty to ninety days' indorsed bills and prime six months' paper were quoted at 6 per cent to  $6\frac{1}{4}$  per cent, as against  $6\frac{1}{4}$  per cent to  $6\frac{1}{2}$  per cent the previous week. While there was a good demand, the supply of high-grade paper was light and was absorbed in the main, it was said, by out-of-town banks.

**Ford August Output to Set New Record**

DETROIT, July 26—Production schedules for August, breaking all previous monthly records, were announced by the Ford Motor Co. to-day.

During August 109,700 cars and trucks are to be made in the United States. The best previous figure is July production, expected to be 109,000. Previous to July, the figures are June, 108,962, and May, 101,464.

The figures given are for the United States alone. The Manchester (England) and Canadian Ford plants expect to increase from 225 cars daily to 300 cars daily during August. No definite schedules have been prepared for these plants as yet, however. This would bring the total world's production of Ford cars and trucks for August to 117,800, surpassing all previous marks.

In addition to the car and truck schedules, it is announced at the River Rouge tractor plant that 200 tractors daily are scheduled for August, or a month's production of 5400 tractors.

Repair parts which would make approximately 150 cars daily are to be produced. The motor production schedule calls for 4200 motors daily.

**GASOLINE STOCKS GROW**

WASHINGTON, July 26—Production of gasoline continues to increase as refinery statistics issued by the Bureau of Mines show that the daily average production for May was 14,469,931 gallons, which is 262,758 gallons larger than the production for the preceding month, and an increase of 1,129,640 gallons over the daily average production for the year 1920. Stocks on hand at the refineries were increased by 55,272,887 gallons over stocks of April 30. The May exports of gasoline amounted to 39,858,771 gallons, while domestic consumption amounted to 354,263,486 gallons. The daily average consumption for the month of May shows a decrease of 318,120 gallons from that for the month of April, also a decrease of 1,703,413 gallons from daily average of May, 1920.

**FINANCIAL NOTES**

General Motors Corp. bank loans now approximate \$66,000,000, a reduction of about \$16,000,000 from notes payable of \$82,000,000 as of December 31 last. Cash on hand is in excess of \$50,000,000, compared with \$47,608,000 seven months ago. Inventories are below \$153,000,000, or \$11,000,000 less than at the beginning of the year. While earnings this year are likely to show a considerable falling off from 1920 net profits of \$37,750,375, or \$1.58 a share on the common after all charges and preferred dividends, indications are that the company's financial position will be a great deal stronger at the end of 1921 than at the close of 1920.

Pierce-Arrow Motor Car Co. shows an operating loss of \$828,866 for the three months ended June 30, after allowing for maintenance and depreciation. This compares with a profit of \$1,432,706 in the corresponding quarter of 1920. Allowances for Federal taxes and other items called for \$571,684 in the second quarter of this year, making a total deficit of \$1,400,550, compared with a surplus of \$705,779 in the three months ended June 30, 1920.

Mason Tire & Rubber Co., in a comparative balance sheet as of May 31, shows cash of \$13,947, against the figures of April 30, 1920, which were \$803,919. Accounts and bills receivable are \$707,722, against \$1,033,149 in April, 1920. Inventories are \$2,628,959, against \$2,245,654 the previous year. Bills and accounts payable amount to \$842,309, in comparison with \$405,228. The surplus is \$126,219, against \$651,538.

Willys-Overland, Inc., of Toledo, has applied for a temporary receiver for the Overland-Houston Co., local distributors of Overland cars. An injunction has been issued restraining the officers of the company from interfering with the assets. Willys-Overland, Inc., the parent company, asserts that it holds a lien on the capital stock of the other concern, the assets of which are estimated at \$130,000.

Sims Magneto Co., in a comparative balance sheet as of December 31, shows cash of \$154,836, as against \$101,858 for 1919. Notes and accounts receivable \$629,394, against \$192,963. Inventories are \$912,842, against \$683,451. Notes and accounts payable \$1,221,908, against \$332,979. The surplus figures are \$590,054, against \$588,393.

Nash Motors Co. has declared a dividend of \$6 a share on the common and a regular quarterly dividend of \$1.75 a share on preferred, both payable August 1.

Wholesale Tire Co., New York, has filed schedules in bankruptcy, listing liabilities of \$55,778 and assets of \$20,323.

Stewart-Warner Speedometer Corp. has declared the regular quarterly dividend of fifty cents on the common stock, payable August 13 to stock of record July 30.

International Harvester Co. has declared a regular quarterly dividend of \$1.75 on the preferred stock, payable September 1 to stock of record August 10.

**RECEIVER FOR OHIO TIRE**

TOLEDO, July 27—William J. Slater, Akron, has been appointed receiver for the Ohio State Rubber Tire Co., Sandusky, by Federal Judge Killits here. Bankruptcy proceedings were started here against the company by Edward Maurer, Inc., of New York, when they filed a bill of complaint.

## MEN OF THE INDUSTRY

L. M. Bradley, of New York, has been appointed sales manager of the New Era Spring & Specialty Co., Grand Rapids, Mich. Mr. Bradley has been in the automotive industry for twenty-two years, his activities dating back to the steam car days. He has been connected with the Willys-Overland, Studebaker, U. S. Motors, R. & V. Knight and for four years was assistant general manager of the old American Motor Car Manufacturers Association of New York, which was formed by Henry Ford to combat the famous Selden patent suit. He has been advertising manager of the "American Motorist" and for three years general manager of the Motor and Accessory Manufacturers Association at New York. He is a former newspaper man.

Major Irving C. Moeller, who has been manager of the Cleveland branch of the Mack International Motor Truck Corp., has been transferred to the general offices of the company in New York. He was guest at a farewell dinner given in Hotel Winton by the Cleveland Automotive Trade Association, of which he was vice-president. M. F. Parsons, manager of the Syracuse branch, Major Moeller's successor, was elected a trustee of the association.

Frank H. Golding, formerly general manager of the Holmes Automobile Co., Canton, Ohio, has been appointed general manager and treasurer of the Fox Motor Car Co. H. O. Swanson, formerly in the service and engineering departments of the H. H. Franklin Co., makers of Franklin air-cooled cars, has been appointed chief engineer. The new plant with 100,000 square feet of floor space is capable of producing 2500 air-cooled cars a year.

Earle S. Barber, who resigned as Director and Sales Advertising Manager of Alfred Decker & Cohn, Chicago, has engaged in business as Earle S. Barber & Co., "Commercial Councillors." They will cover the various branches of business and will maintain a sales organization for obtaining distribution and maintaining efficient representation in five states—Illinois, Indiana, Iowa, Michigan and Wisconsin.

W. R. Hyde, for several years special Western representative of Hilo Varnish Corp., with headquarters in Chicago, will take over the New York and Pennsylvania territory, formerly covered by J. Frank Brown. The new territory, which is not new to Hyde, as he looked after it in former years, will offer a splendid opportunity for the development of business in the industrial field.

George R. Wright, who for the past eight years has been manager of the Philadelphia branch of the Chevrolet Motor Co., has been appointed distributor for the new Durant line in Philadelphia and the surrounding territory. The present home of the Oakland car at 918 North Broad Street has been leased by Wright for a term of years for the Durant.

George T. Briggs is again connected with Wheeler-Schebler Carburetor Co., Indianapolis, as general sales manager. Briggs was associated with the Sinclair Refining Co. as manager of the Automotive Division, and more recently as general manager of the Motorcycle and Allied Trades Association.

Arthur H. Lacey, formerly assistant director of engineering with the Hall-Scott Motor Car Co., and who is now a consulting engineer in Oakland, California, has taken larger offices where with increased facilities,

he states that engineering problems will be taken care of most efficiently.

Vance McCarty, one of the most prominent men in the leather belting industry, has been elected vice-president of the Chicago Belting Co. He leaves the Edward R. Ladew Co., Inc., of which he was vice-president.

K. H. MacQueen has been appointed assistant to the general manager of the Bearings Service Co., at Detroit. MacQueen was associated with the Bearings Service Co. at the time it was formed.

## INDUSTRIAL NOTES

Frank B. Anstead, president of the United States Automotive Corp., has announced the formation of the Fayette Painting and Trimming Co., a new subsidiary of the automotive corporation, with a capital stock of \$500,000 in common shares. The new company will engage in the painting and trimming of the bodies for the Lexington Motor Co., which is the principal subsidiary of the United States Automotive Corporation.

Bantam Ball Bearing Co. announces that widespread distribution has resulted in a demand for replacement bearings and the company has just added a replacement department to its organization. J. H. Kraus, in charge of this department, is now arranging with dealers throughout the country to carry a stock of various bearing applications for replacement service.

Positive Lock-Bolt Co. has purchased the entire assets of The Safety Nut & Bolt Co. The new organization is a \$250,000 Ohio corporation, with the following personnel: C. C. Murphy, president; J. N. Leatherman, vice-president; M. D. Neff, secretary; Edna B. Craft, treasurer; W. H. Burke, general manager; H. L. Jollay and Wm. F. Koehn, directors.

American Malleable Co., Owosso, Mich., has opened one furnace giving employment to 150 men. This makes the number of men now employed by the factory 300. The recent increases in business have come from the Buick plant which is increasing materially its production. The local plant furnishes several parts for the Buick car.

Collapsible Rim Corp., New York City, has announced full production of Standard collapsible rims in all the popular sizes. The rim is indorsed as being thoroughly practical and scientifically right. It operates in an entirely new manner and is said to relieve the motorist of all the annoyance that follows tire trouble.

American Motor Body Co. has filed plans for an addition and other improvements for the works of the Hale & Kilburn Corp. at Philadelphia.

Webster & Perks Tool Co. has sold its grinding and polishing stand and accessory department to the Hill-Curtis Co., Kalamazoo, Mich.

## CREDIT CONDITIONS BETTER

INDIANAPOLIS, IND., July 20—Credit conditions are improving materially, according to executives of the various automobile financing organizations of this city. Collections in every one of the companies now are approaching the 100 per cent mark.

## Interest Is Centered on U. S. Air Policies

### President Understood to Favor a Central Bureau of Aviation for Country

WASHINGTON, July 19.—Considerable interest is being manifested as to the air policy the Government may adopt in connection with the work of reorganizing the different departments, which is now well under way. There can be no question that difference of view obtain, but it is understood that the President is in favor of creating a central bureau of aviation, which might be established in some Government department rather than as an individual unit.

It is known to be the opinion of the Administration that a distinct aviation bureau would develop more creative genius as well as economy than is possible now under the present system of having different aviation services under various bureaus, such as the War, State and Post Office departments. There can be no doubt that study of the aviation problems has convinced the Government of the desirability of establishing a commercial aircraft industry on a paying basis, not only because of its importance to trade and business in peace times but because of its availability in times of emergency. Among the problems that have presented themselves, however, is that of maintaining production sufficient to encourage different concerns to engage in the industry. This, of course, would require the distributing of awards for aircraft, and it is stated that it has not definitely been determined how the Government may aid in this direction.

Plans for reorganization of the Government departments, while progressing, have not as yet reached a point where specific recommendations have been determined upon in regard to the establishing of a fixed air policy, but it is believed that the organization of a central bureau will result.

President Harding has nominated Capt. W. A. Moffett as Chief of the Navy Department's Bureau of Aeronautics with the rank of rear admiral. Capt. Moffett has been interested in aviation for several years and is at present in charge of the naval aviation here.

## JORDAN GOING CAPACITY

CLEVELAND, OHIO, July 26—Distributors here at a meeting at the factory of the Jordan Motor Car Co. were told that factory capacity for the next four months has been sold and that production will be maintained at the organization's highest average. The Jordan Co. during the quarter just ended shipped ten per cent more cars than in the same period last year, which was the peak of the automobile sales boom. Distributors reported fewer cars on their floors July 15 than at any previous time in the company's history. This is attributed to the sales increase which followed the price reduction in May.

# Calendar

## SHOWS

Sept. 5-10—Indianapolis, Automobile and Accessory Show in conjunction with Indiana State Fair, conducted by Indianapolis Automobile Trade Association, John B. Orman, Mgr.

Sept. 23-Oct. 8—New York, Electrical Exposition, 71st Regt. Armory. Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 2—New York, Automobile Salon, Hotel Commodore.

January—Chicago, Automobile Salon, Hotel Drake.

Jan. 7-13—New York, National Automobile Show, Madison Square Garden, Auspices of N.A.C.C.

Jan. 28-Feb. 2—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.

Sept. 9 to 17—Ottawa, Ont., Can.—Ottawa Motor Show.

Feb. 6 to 11—Winnipeg, Can., Automotive Equipment Show, Western Canadian Automotive Association.

## FOREIGN SHOWS

September—Buenos Aires, Argentina, Passenger Cars and Equipment. La Paellon de las Rosas. Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery. Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Sept. 5, 1921—Constantinople, Traction trials under the direction of the Turkish Ministry of Agriculture.

Sept. 23-Oct. 2—Berlin, German National Automobile Show, Auspices of German Automobile Mfg. Ass'n and German Automobile Club.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.

March, 1922—Santiago, Chili, Annual Automobile Show.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

Sept. 1922—Rio de Janeiro, Brazil, Automobile exhibits in connection with the Brazilian Centenary Association Automobilista Brasileira.

## CONVENTIONS

Sept. 14-15-16—Portland, Ore., Credit Convention Motor and Accessory Manufacturers Association.

Oct. 12-14—Chicago, Twenty-eighth Annual Convention National Implement & Vehicle Ass'n.

Nov. 22—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

## RACES

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

## No More Price Cutting, Says President Willys

TOLEDO, OHIO, July 26—In discussing the price question upon his arrival for a few days' consultation with factory officials, John N. Willys said:

"I have been asked several times lately about the future price situation. So far as we are concerned it is very simply answered; there have been one or two so-called second cuts on certain automobiles which in reality were just a slight trimming down of prices. When we decided to reduce our price we went all the way. The present extra price of \$695 on Overland is a reduction of approximately 33 per cent. We made this reduction because we wanted to get the benefit of big volume business and we are getting it.

"I am confident that the financial interests of the country will continue to do their best to support legitimate, hard working dealers in maintaining the proper stock of automobiles and I know the dealers who have automobiles on hand can sell them and are selling them.

"I believe, however, that a complete evolution in the method of selling automobiles is in progress. Dealers and distributors are conducting their business on sounder lines. They are systematically going after business and watching their costs in a way they never did before."

## 7 Goodyear Directors Elected in Dominion

TORONTO, ONT., July 26—The special general meeting of Goodyear Tire & Rubber Co. of Canada, for the purpose of electing seven directors under the new plan, four by common and three by preferred and prior preferred shareholders, resulted in the election of, for the common, A. H. Carlisle, E. G. Wilmer, G. M. Stadelman and P. W. Litchfield, and for the preferred, B. A. Thompson, of Nesbitt & Thompson, Montreal; J. A. McAllister, nominee of Dominion Securities, Toronto, and J. G. Lane, present secretary of the company.

In answer to questions raised by a few preferred shareholders, General Manager A. M. Carlisle stated that the issue of 6 per cent prior preferred stock had all gone to the parent Akron company at par in liquidation of indebtedness. The sum issued was \$2,826,000, as against an authorization of \$4,500,000, which had been legalized, but which had not all been required, and the balance of which was not for sale. Mr. Carlisle also stated definitely that not one share of common had been bonus stock. Every dollar's worth had been issued for value received or interest due. This common stock was cut from \$100 to \$10 par in the course of the reorganization.

## Buys Rubber Company, Pays \$22,422.93 Taxes

COLUMBUS, July 20—By a decision in the Federal Court in Columbus, the Allen Motor Co. will be compelled to pay \$22,422.93 in Federal income taxes which was assessed against the Scioto Rubber Co. Although the decision is local, the effects are far reaching and will affect many similar cases.

The Allen Motor Co. took over the plant and property of the Scioto Rubber Co. April 29, 1919. In the article of agreement the Allen company assumed all of the legal debts of the rubber company. After the purchase Federal agents found that the income tax unpaid for 1917 was \$3,304.76 and for 1918, \$19,117.17. The Scioto Rubber Co. was no more as its assets had been merged with the Allen Motor Co.

## Stratton-Bliss Gets Dodge

NEW YORK, July 20—The Stratton-Bliss Co., holding the Dodge Brothers franchise in New York City, has discontinued its contract with the Elsey Motor Co., which had the Dodge in the Bronx. Both sales and service will be handled at the Stratton-Bliss branch, Grand Concourse. Charles J. Quinn, who has been with the headquarters sales department of Stratton-Bliss on Broadway, has been made manager of the branch.

## Standardized Traffic Adopted in Bay State

BOSTON, July 26—Motorists traveling throughout Massachusetts in the near future will not be mixed up on traffic signals, for plans have been outlined whereby the different police departments will adopt standardized regulations to govern traffic. This was brought about as a result of a conference yesterday at the Massachusetts Automobile Club attended by more than 100 chiefs of police and representatives of the Safe Roads Federation.

Following an all day session it was voted to appoint a committee to take up the matter. This committee comprises Chief Michael Feeney of Fall River, chairman; Deputy Chief Thomas McMurray of Worcester, Chief Edward P. Doherty of New Bedford, Chief James H. McKenna, Waltham, Capt. Bernard J. Hoppe, Boston Traffic Squad, and Capt. George A. Parker of the State Motor Patrol.

The conference voted also that it was the sense of the meeting that in the opinion of those present:

Motorists who drive under the influence of liquor should be sent to jail instead of being fined.

Pedestrians should be made to cross the street at protected crossings in the interest of safety.

## See Reduced F.O.B. Rates in Proposed Schedule

ATLANTA, GA., July 26—Material reduction in the f.o.b. rates from the Central Freight Association, or automobile, territory to Atlanta may be effected if the new schedule of freight rates for the Southeast is adopted, it was indicated at a conference of shippers and carriers held recently in the Chamber of Commerce, Atlanta.

The new rate scale was introduced in the proceedings by B. M. Goodwyn, chairman of the fourth section committee of the Interstate Commerce Commission.

## Nine Out of Ten People Are Buying "Fours" \*

**T**HE multi-cylinder cars have a distinct place in the automobile market, from which they cannot be displaced.

Yet their market is not only small, but is essentially different from the big, broad market where the initial investment is more of a determining factor of choice.

In this big market competitive models have been less numerous among the "Fours," a fact of importance to the car manufacturer.

Only 35% of all makes are "Fours," but 90% of all cars sold are "Fours."

This increasing preference for "Fours" by the buying public is undoubtedly due to the fact that, with the right four-cylinder motor, the car manufacturer can offer all of the essential things any motor can do and at the same time build appealing quality and value into the rest of the car to a degree impossible with more cylinders at the same price range.

In an unusual way, the Lycoming Motor qualifies for leadership among the four-cylinder engines.

Find out about this four-cylinder engine—Model K, Lycoming Motor.

## FEDERAL BEARINGS

### UNIFORMITY

The Babbitt lining in every Federal Bearing shows the same tough, fine-grained, homogeneous structure because every Bearing is chilled immediately after it is lined.

### SOLIDITY

Every Federal Bearing is guaranteed absolutely free from porosity, because the process of manufacturing makes it impossible for the Babbitt to contain air while cooling.

### 100% BOND

Unlike all other methods of manufacturing Bearings, the Babbitt lining and Bronze Back of every Federal Bearing is Bonded UNDER PRESSURE while the adhering alloy is at a constant temperature.

### EXCELLENCE

Every Federal Bearing is manufactured from the highest grade materials, machined accurately and subjected to the most rigid inspection, because "FEDERAL, DETROIT" must be stamped on the back.

EVERY FEDERAL BEARING IS LINED BY

## CENTRIFUGAL FORCE

## Trends in the Petroleum Industry for First Half of 1921

Production and imports of crude, and consumption of gasoline exceed figures for first half of 1920. Imports from Mexico which are now falling off, have prevented possible shortage in total supply here.

By Joseph E. Pogue<sup>1</sup>

**T**HE petroleum industry was among the last to be affected by the industrial depression.<sup>2</sup> Although showing signs of succumbing in late 1920, the industry had gathered so much momentum that it ran over into 1921 before the reaction fully came. In February, however, a sharp break in prices occurred and from then on the process of general liquidation was drastic.

But in spite of all depressing influences, the actual production of crude petroleum, under the impetus gained in 1920, has gone on increasing; and even petroleum refining, closely linked with crude production, has displayed only a moderate curtailment, as compared with the recession in manufacturing activities in general. Thus large stocks of both crude and refined products have accumulated.

A unique factor in the petroleum situation is an increase in the demand for one of the products, gasoline, accompanying greatly lessened requirements for kerosene, fuel oil, and lubricating oils

—an unbalanced market condition which has created perplexing problems.

Coincident with full production at home and a set of demands badly out of balance, the oil fields of Mexico have been exploited with redoubled intensity, under the spur of a keen competition and the menace of salt water encroachments. In consequence, a flood of imported oil has come upon the domestic market to add to the demoralization.

The feature of greatest interest to the automotive industry is the now well demonstrated fact that petroleum, because of peculiarities incident to its exploitation, does not conform closely to the economic cycle, but displays a lag of some six to twelve months.

That is to say, at any given moment the production of crude petroleum (and refinery activity to a modified extent) is responding to the stimulating or depressing influences of conditions months in the past. Thus during the first half of 1921, a period when production in general was running at half capacity, the output of crude petroleum broke all previous records.

Conversely, at the next turn ahead, when demands revive, the output of crude petroleum may be expected to display the deferred effects of the present time of depression.

<sup>1</sup> Consulting Engineer, New York.

<sup>2</sup> The statistics presented in this review were derived from the following sources: Data on crude petroleum from U. S. Geological Survey and American Petroleum Institute; refined products from U. S. Bureau of Mines; well data from Oil and Gas Journal; export figures from U. S. Bureau of Foreign and Domestic Commerce; prices calculated by the writer from quotations given in The National Petroleum News, and The Oil, Paint, and Drug Reporter.

The production of crude petroleum in the United States increased from 211 million barrels during the first half of 1920, to 237 million barrels in the first six months of 1921—an advance of 12 per cent. At the same time the corresponding imports of crude petroleum grew from 39 million barrels to 66 million barrels. These imports came practically entirely from Mexico. The consumption of crude petroleum during the two half-year periods under view increased 5 per cent, but this change is scarcely a measure of demand since part of the petroleum consumed by refineries went merely into the building up of stocks of refined products. A review of the crude petroleum situation is presented in Table I.

Of greater significance than the half-year record is the trend of the significant items, and the course of production and imports of crude petroleum in the United States by months for the period 1918-1921 is shown in Fig. 1. The chart is drawn on a ratio scale in which the slopes of the curves are proportional to the percentage changes.

The failure of the curve of production to accommodate itself to the depressed demand of the current year is at once to be noticed, as well as the prominent part played of late by imported oil, that is, Mexican petroleum. Imports reached their peak in late 1920, but the decline in 1921 has not been great relative to the lessened requirements.

#### Oil Field Development

The production of crude petroleum is composed of the declining output of thousands of old wells plus the flush production of hundreds of new wells. The country's outflow of petroleum would gradually decline, were it not for the complement of new wells brought in each month. A study of drilling activity, therefore, gives a clew to future production, since the rate of decline of old wells is known.

During the first six months of 1921, there were 2675 fewer productive wells completed in the fields east of California than during the same period of the previous year. The total number for 1921 (6 months) was 8568, as compared with 11,243 in 1920 (6 months). The number of rigs up and wells drilling—an index of the work under way—has fallen from 11,087 in June, 1920, to 6418 in June, 1921. The main effect of this recession in preparation for production is yet to be felt.

The trend of new work and successful completions in the entire country exclusive of California is shown by months for 1920 and 1921 (6 months) in Fig. 2. The ratio scale permits the slopes of the two curves to be directly compared.

It is at once apparent that drilling activity has fallen away nearly 50 per cent since its period of greatest intensity in 1920. The significant feature, however, is that the present decline is over the summer months (when drilling efforts are normally at their height) and during the coming winter the seasonal decline will still further cut down operations. Thus a gap is created in the productive effort that can be made up with difficulty when an increasing production comes to be required.

During the past few months there has been a change in the type of territory subjected to drilling. Ordinarily, a large share of drilling efforts are directed to pioneer acreage.

Of late, under the low prices prevailing, the drill has been directed almost wholly to proven acreage where the chances of striking oil are good. The net effect has been an intensive development of blocked-out reserves. Such a policy, if long continued, will seriously retard the gaining of an increased production later on.

During the year two new oil pools were opened up—the El Dorado in southern Arkansas and the Haynesville in northern Louisiana. During the week ending July 9, the estimated daily output of these two pools was 52,000 and 10,450 barrels respectively, together 4.76 per cent of the country's total production. The development of these two pools has contributed substantially to the increase in domestic production that has characterized the first part of 1921. The bringing in of new territory at a time when the oil was not needed reflects the tendency of petroleum production to proceed independently of outside conditions.

#### Mexico

The production of crude petroleum in the United States for a number of years has fallen short of domestic requirements, not through any failure on the part of production, which has gone on increasing, but because demand has been growing at a rate which could not be paralleled by output. The degree to which this country has grown into petroleum dependence upon outside sources of supply is indicated by the fact that at the beginning of 1921 one-fourth of our crude petroleum was coming from Mexico. This proportion fell to about one-fifth during early 1921, but without imported oil even the depressed demands of middle 1921 could scarcely have been satisfied.

In view of the important bearing of Mexican petroleum upon industrial and automotive activities in the United States, the reports as to the rapid exhaustion of the producing pools in Mexico have proven disquieting. It is not generally realized that the proven oil pools of Mexico are confined to a small area in the Tampico-Tuxpam region, which was responsible for a quarter of the world's output of petroleum in 1920. Outside of this single area, there are promises of oil in several localities, but as yet no important commercially developed deposits; relatively little development work, in fact, has been done outside the proven area, which will have a retarding effect on future production.

Widespread attention was attracted by an address on the oil situation made by Ralph Arnold, a prominent petroleum engineer, before the American Institute of Mining and Metallurgical Engineers on February 16, 1921, in which the following statement was made regarding the proven oil pools of Mexico:

"Now let us turn to some concrete figures regarding the immediate future in Mexico: There have been twelve proven important pools: Ebano, Panuco, Topila, Dos Bocas, Tepatate, Casiano, Chinampa, Los

Naranjos, Zacamixtle, Cerro Azul, Potrero del Llano and Alamo. Of these Dos Bocas, Tepatate, Casiano, Chinampa and Potrero del Llano are extinct; Los Naranjos, Panuco and Alamo are rapidly going to salt water, and, with the exception of Panuco, as far as important production is concerned, are, or soon will be, unimportant. Panuco and Ebano, apparently will continue for many years producing enough oil and a valuable mixture of oil and water to have an important bearing on the productivity of Mexico. This leaves Zacamixtle, a practically virgin pool, and Cerro Azul, a partly exhausted pool, the latter controlled by a single company, to furnish, with Panuco, the bulk of the proven future supply. Of the exhausted pools, the greatest only produces a little over 120,000,000 barrels. Los Naranjos will probably produce a total of over 150,000,000 barrels. These oil pools compared favorably in area with the present producing pools, so that these latter may be assumed to yield no large excess over the maximum so far attained. Estimates of future production are: Zacamixtle, over 125,000,000 bbl.; Cerro Azul, 75,000,000 bbl. remaining; Alamo, 25,000,000 bbl. remaining; Los Naranjos and Panuco, each 50,000,000 bbl. remaining; total, 325,000,000 bbl. Last year Mexico produced 185,000,000 bbl., or an average of about 500,000 bbl. per day. Mexico is now producing at the rate of about 600,000 bbl. per day; approximately two-thirds of this is com-

ing from Los Naranjos, a pool which will probably be extinct by early summer on account of the encroachment of salt water. If the present rate is maintained throughout the year, 1921 will see about 220,000,000 bbl. of oil brought to the surface in Mexico, or about one-half the probable production of the United States for the year. But Mexico's proven reserve is less than twice this amount, hence, at the present rate of production, the latter part of 1922 will see the end of the proven big fields in Mexico. There is little wildcatting going on in Mexico now, probably not over 25 strictly wildcat wells now being actively drilled outside the main producing district. Whether it is 1½ years or 2 years, or even a little longer or a little less before the break comes, it is certain to come."

The reader should hold clearly in mind that the statement quoted above refers to the proven oil pools of Mexico. Other deposits will certainly be developed in Mexico, but the pools now contributing so bountifully are not limitless and are showing signs of approaching exhaustion.

Arnold's analysis has aroused considerable discussion and difference of opinion. While some of the proven pools referred to may be extended by further drilling and the limits of the Zacamixtle pool have apparently

<sup>1</sup> The Oil Situation, Mining and Metallurgy, Mar., 1921, pp. 20-21.

Fig. 4—Production of petroleum products in the United States during the first six months of 1920-1921

already been enlarged during the first six months of 1921, the statement by Arnold is deserving of close consideration.

Should the curve of Mexican production turn sharply downward in 1922 or 1923, the effect upon the petroleum situation in the United States will be significant.

#### Refinery Activity

The best index of refinery activity is the quantity of crude petroleum run to stills and the trend of this factor by months is reflected in Fig. 3. Reference to this chart will disclose the rapid increase in refining activity throughout the second and third quarters of 1920; the maintenance of a high level of productivity the fourth quarter; and a slight recession during the first half of 1921. The moderation of the curtailment in crude run to stills in early 1921 is striking, in view of the drastic recessions both in productive activities in general and in demands for most of the petroleum products. The relatively vigorous status of petroleum refining was due partly to the attempt of refineries to accommodate producers and in part to the increased demand for gasoline

Fig. 5—Trend of the gasoline situation by months, 1917-1921

which could not have been met if refinery output had been trimmed to the measure of the market for kerosene, fuel oil, and lubricants.

On January 1, 1921, there were 415 refineries in the United States with a daily capacity of 1,888,800 barrels, as compared with 373 refineries with a daily capacity of 1,530,565 barrels a year previous. During 1920, therefore, refinery capacity in the United States increased 23 per cent.

On January 1, 1921, the proportion of the installed capacity being utilized was 68 per cent. As refining was virtually at its highest point at this time, the figures quoted indicate the extent to which the refining industry was overbuilt relative to normal requirements.

The output of the leading petroleum products—gasoline, kerosene, fuel oil, and lubricating oils—for the first six months of 1921 as compared with the corresponding period of 1920, is given in tabular form in Table 2 and shown graphically in Fig. 4. It will be observed that gasoline and fuel oil have increased in output 19 per cent and 21 per cent respectively; while kerosene and lubricating oils have declined. This differ-

ence reflects the lack of balance obtaining between the several demands for petroleum products.

### Gasoline

The trend of the gasoline situation by months from 1917 to the present is shown in Fig. 5. The chart is drawn on a ratio scale so that the percentage changes as well as the quantity changes may be directly observed and compared.

The trend of the output of gasoline over the period shown indicates an annual increase of approximately 18 per cent; this rate also measures the increase in demand. The gasoline requirements of the current year show some recession from the past trend, though they are still 10 per cent in advance of the requirements of a year ago. An increase of this magnitude in the domestic demand for gasoline during a period of industrial depression is a striking commentary on the essential character of automotive transportation.

The marked seasonal character of the curve representing gasoline stocks is noteworthy. In spite of the current increase in gasoline requirements, production this year has been amply maintained. Gasoline stocks usually start to decline in April, but this May saw a sharp increase instead of the usual recession. The flexure in the curve reflecting this feature is an indication of the extent to which the petroleum industry has maintained production in the face of a general industrial decline.

The United States Bureau of Mines conducted its usual semi-annual chemical survey of motor-gasoline in January and the summarized results are shown comparably in Table 3. It will be noted that the average

Fig. 6—Trend of the average prices of gasoline, kerosene, and lubricating oils by months, 1917-1921

indeed, has proved an embarrassing problem to many refiners, and in some quarters the product has been lumped with fuel oil in the absence of an adequate market for its separate disposition.

Fuel oil has also been piling up on the refiners' hands because of the curtailment in industrial and shipping activities. Much of the imported crude is turned into this product and it is also produced perforce in the manufacture of gasoline. The close relationship between gasoline and fuel oil as joint-products always causes trouble when the demands for the two get out of step.

The demand for lubricating oils suffered serious curtailment during 1921, following closely upon the marked stimulation in output that characterized 1920. Between September 30 last and April 30 the stocks of lubricating oils on hand in the United States have doubled.

### Exports

In common with other productive activities, the petroleum industry has suffered from a sharp decline in its export trade. This condition has proved particularly troublesome in respect to kerosene and lubricating oils, the two products that normally go abroad in greatest proportion.

Exports of the four major products of petroleum for the first half of 1920 and 1921 are compared in Table 4, where the degree of the recession in the foreign demand is at once apparent.

The vigorous entry of foreign countries into oil field development may be expected to bring growing competition into the overseas markets for oil products and thus restrict this outlet for American oils.

### Prices

As may readily be gathered from the foregoing discussion, the price situation in the petroleum industry has undergone a radical revision during the first six months of 1921. This situation is depicted in perspective in Fig. 6, where the trend of the average prices of gasoline, kerosene, and lubricating oils is shown by months from 1917 to the present. The sharp advances gained in

TABLE 4—EXPORTS OF PETROLEUM PRODUCTS DURING THE FIRST 6 MONTHS OF 1920 AND 1921  
(In millions of gallons)

	First 6 months, 1920	First 6 months, 1921	Per cent change

Kerosene .....	424	386	- 9%
Gas and fuel oil.....	411	436	+ 6%
Lubricating oils .....	209	137	-34%

endpoint was approximately the same in January, 1921, as in January, 1920, and notably less than in July, 1920. The average endpoint of gasoline is always less in winter than in summer by virtue of the lessened demand in cold weather; but the normal increase in endpoint that has characterized the past five years is slowing up this year in keeping with an "easy" supply. The endpoint of gasoline is a function of the degree of stress between supply and demand, modified by the season. If its past behavior is any criterion of the future, the endpoint will reassume its upward trend as soon as demand begins again to take the lead over supply.

### Other Products

The production of kerosene has fallen rather sharply throughout the first six months of 1921, in keeping with a much reduced demand. The disposition of kerosene,

*All commodities.....	100	212	250	269	251	207	169	151

\*From U. S. Bureau of Labor Statistics.

early 1920 have been eliminated and petroleum prices have gone far toward their pre-war level. Thus in June of this year, the prices of mineral oils stood as follows, in percentages of the average prices prevailing in 1913: Crude petroleum, 127; gasoline, 137; kerosene, 146; fuel oil, 102; lubricating oils, 154.

Fig. 6 indicates that the average price of gasoline in June, 1921, was approximately equal to the average price over the three year period, 1917-1919. The price of lubricating oils, it may be observed, started downward the middle of 1920, shortly after commodity prices in general started to decline, and between June, 1920, and June, 1921, fell 58 per cent. The steady upward trend of the price of kerosene from the beginning of 1917 to late 1920 should not escape attention, as this move toward the level of gasoline was caused by the entrance of kerosene into use as a motor fuel.

The price of mineral oils compared with all commodities is shown by quarters in Table 5, in percentages of the prices prevailing in 1913. These composite figures are calculated from thousands of individual quotations and reflect with considerable verity the country wide levels attained during the period shown. The drastic liquidation in petroleum prices *per se* and relative to prices in general is definitely measured.

The actual prices of gasoline in a number of selected cities is given in Table 6 by months for 1921, compared with the average prices in 1913, 1919, and 1920. While gasoline has a smaller percentage decline than its joint products, it had previously attained a less high level from which to recede. The marked difference in level in various parts of the country is noticeable, the product being cheaper in the central states, where the bulk of the gasoline is produced.

Petroleum prices for a time were resistant to the downward price swing that accompanied the industrial

depression, but they finally succumbed and soon made up for lost time in their downward course.

### Conclusions

The features of the half-year of special interest from the automotive viewpoint may be summarized as follows:

- (1) The domestic production of crude petroleum continued to increase despite a sharp decline in prices and demands.
- (2) Prices of crude petroleum and its products displayed a sudden and spectacular recession.
- (3) Oil field development suffered a notable curtailment, with an effect still to be felt.
- (4) The stocks of both crude petroleum and its products accumulated in considerable volume.
- (5) Refinery activity slowed down very slightly, considering the decline in the market.
- (6) Mexico attracted widespread attention in respect to the encroachment of salt water in many of her wells.
- (7) Export activity fell away to a consequential degree.
- (8) Two new domestic pools were vigorously developed at an inopportune time.
- (9) Petroleum came to the forefront as an international problem.

### Fuel Developments Abroad

ONE of the last acts of the French Chamber of Deputies before adjournment was to authorize the Minister of Commerce to proceed with the production of the "native motor fuel" which is to be a substitute for gasoline and render France independent of Great Britain and the United States in this respect. This fuel is said to be the result of extended research work carried on at Government laboratories. René Faber, an engineer, is said to have succeeded in producing alcohol anhydrate, that is, alcohol combined with gasoline, which is then treated with acid and redistilled.

From Germany comes news of a new motor fuel named Tetraline. It is a by-product of the process of making coke from bituminous coal. One molecule of naphthalene, the coal tar product formerly used for making dyes, is combined with four atoms of hydrogen. The resulting product is technically known as tetra-hydronaphthalene, but for commercial purposes the name has been shortened to tetraline. It is a liquid as clear as water, with a specific gravity of 0.975. The boiling and ignition temperatures are both very high, and the freezing temperature is very low. These properties are said to make the new fuel particularly suitable for use in small bore, high speed engines. Owing to the high ignition temperature the fuel cannot well be used in low compression engines, but when mixed with somewhat more volatile fuels it can be used in the average gasoline engine, according to the inventors.

# Highway Transport the Greatest National Economic Problem

Thirty educators and industrial leaders discuss importance of proper educational training for men who are to adjust this growing industry to the public needs. Highways and their use considered as one problem.

**T**HE proper construction and use of the highways is the greatest single economic question before the people to-day, was a statement frequently made at a recent gathering of economists at the University of Maryland. The meeting had been called by the Committee on Highway and Highway Transport Education with a view to getting expressions of opinion from engineers engaged in educational work, manufacturers and users of highway transport with the ultimate purpose of outlining an engineering educational course that can be recommended to universities interested in this line of work.

It was said repeatedly that the financing of highway projects had been a sort of haphazard affair which had borne good results on a wave of popular opinion in favor of good roads, but that, as many of the States and other civil divisions are nearing their legal limit of indebtedness for this purpose, more orderly methods of finance have to be found. The foundation of motor transport, of course, is based on the actual highway and without proper highways there can be no effective motor transport. Motor transport, in the minds of the men assembled, is of equal importance with that of any other branch of transportation and will, eventually become the vital link, as it is the feeder of railway and all other transportation. It was admitted by all concerned that at present much of the highway transportation is uneconomical because there is not the proper understanding of its importance to the public life and because of the small development of basic knowledge concerning it.

The topics on the program are illustrative of the objectives of the committee:

- Highway Transport
- Highway Finance
- Economic Problems of Construction and Maintenance
- Highway Administration
- Cost Accounting in Highway Transport Operation
- National and State Legislation

C. J. Tilden, Director of the Committee, called the meeting to order and introduced President Charles S. Howe of the Case School of Applied Science who served as chairman of the meeting.

A better understanding of the deliberations of the meeting probably will be gained through including here a list of those present:

- A. F. Woods, President, University of Maryland.
- George H. Pride, President, Heavy Haulage Company.
- E. G. Sutton, Executive Secretary, National Association of Sand and Gravel Producers.
- George A. Ricker, District Engineer, Portland Cement Association.
- J. C. Marquis, Editor, *Country Gentleman*.
- J. N. Mackall, Chairman, Maryland State Roads Commission.
- W. E. McComas, Portland Cement Association.
- W. K. Hatt, Professor of Civil Engineering, Purdue University, and Director, Highway Research, National Research Council.
- J. C. Long, Educational Secretary, N. A. C. C.
- W. C. John, United States Bureau of Education.
- T. W. Allen, General Inspector, Bureau of Public Roads.

- N. W. Dougherty, Professor of Civil Engineering, University of Tennessee.
- H. G. McGee, Bureau of Municipal Research.
- W. A. Bassett, Chief, Engineering Division, National Institute of Public Administration.
- F. W. Fenn, N. A. C. C. Truck Committee.
- George F. Zook, Chief, Division Higher Education, Bureau of Education.
- W. T. Bawden, Assistant to Commissioner, Bureau of Education.
- P. P. Claxton, formerly U. S. Commissioner of Education, Provost-Elect, University of Alabama.
- J. G. McKay, Professor of Economics, University of Wisconsin.
- Charles S. Howe, President, Case School of Applied Science.
- H. G. Collins, The White Company.
- E. J. Adams.
- T. H. MacDonald, Chief, Bureau of Public Roads.
- M. O. Eldridge, Director of Roads, A. A. A.
- Maj. F. S. Besson, Corps of Engineers, U. S. Army.
- Clyde Jennings, Managing Editor, *AUTOMOTIVE INDUSTRIES*.
- J. R. Bibbins, Department of Transportation and Commerce, U. S. Chamber of Commerce.
- A. J. Brosseau, President, International Motors Company.
- A. M. Loomis, National Grange.
- L. M. Estabrook, Associate Chief, Bureau of Markets and Crop Estimates, Department of Agriculture.
- Charles L. Raper, Dean, College of Business Administration, Syracuse University.
- Pyke Johnson, National Automobile Chamber of Commerce.
- R. D. Chapin, President, Hudson Motor Car Company.
- A. N. Johnson, Dean, College of Engineering, University of Maryland.
- R. A. Hauer, International Motors Company.
- J. W. Brooks, Director, American Highway Educational Bureau.
- C. J. Tilden, Director, Highway and Highway Transport Education Committee.
- C. D. Curtiss, Bureau of Public Roads.
- S. S. Steinberg, Professor of Civil Engineering, University of Maryland.

This group of men, of course, did not gather to study the petty questions that are bothering the truck operator of to-day, nor were they interested in the troubles of any one road man. They were gathered to throw all troubles into the melting pot and to consider the proper method of solving the general highway transport problem of the future.

The suggestion that highway financing plans are in a bad way was made by MacDonald. He told of States and communities that are nearing their debt limit and of projects which are being held up because the bonds cannot be sold at the rate of interest authorized. This fact was referred to many times during the day. McKay, the Wisconsin University economist who is doing consulting work for the Bureau of Roads, read a paper in which he presented a new plan for the allotment of costs, according to benefits accruing. He advocated some radical departures from the present method of assessment and advocated a heavier burden on the present users of highways. His plan was not presented as a finished one but a tentative plan subject to further development. As a final thought, Adams suggested that it might be possible to put the present authorized highway bonds in a fund for which Fed-

eral currency might be issued, under the authority of the War Finance Board. His thought was based on the recently announced plan to assist the railroads. He held that highway transportation is as vital to the country as is railroad transportation—a conclusion in which all present agreed.

#### Old Roads as Foundation for New

Mackall gave a new turn to the thought on financing when he said that too many roads which would serve perfectly well as foundations are being torn up to build entirely new roads. He told of work done in Maryland where roads that had been broken up under the heavy war time traffic between Washington and Philadelphia had been resurfaced at much less cost than a new road and are perhaps better than entirely new roads. His point was that engineers are sometimes overlooking assets in the present wornout highways.

Brosseau, speaking on financing, asked for closer inquiry into the needs of the community and the building of roads equal to the traffic that could be expected. There is an inclination to build for a greater need than exists, he thought, in this way wasting money and turning the taxpayers against the project.

Eldridge of the A. A. A. spoke of the need of a uniform traffic census system, as it is impossible to compare present census. Dougherty thought that the very basis of a highway course should be studied as to cost of maintenance, construction and the traffic census and the relation of the cost and expectancy to the property.

Dr. Claxton was impressed with the additional factor of value in the social advantages of a good highway system and asked that this be considered. He spoke of the satisfaction he felt in that the subject of transportation had been injected into the educational system during his term of office. He urged that the continuance of this work be supported as much good could be accomplished by the proper education of children both in an appreciation of the necessity of transportation and in safety. The actual nationalization of education on this subject in common with others must, he thought, come through the State universities.

#### National Viewpoint Important

The need of a nationalization of thought and action on highway and highway transport was suggested by Chapin and this fact, too, was brought out by others many times during the day. Chapin said that the time has come when roads must return the cost dollar for dollar. In the past the money for construction had come too easily but that 21 billion of dollars had been invested in highway transport and it is time the subject was taken more seriously. The present maintenance, he said, was equal to that of railroad transportation, about 10 billion of dollars a year. The need now is for a national view of this question. Railroad and highway transportation should be considered together as transportation necessary to the prosperity and welfare of the nation. He said that in the study of highway transport, attention had been given to the truck alone but that it is necessary to include the passenger car which has become a vital factor in every-day life and which, through better manufacture and lower price of the next few years, will become even more closely entwined into daily life. The number of passenger cars traveling daily, he said, has become a problem that can not be ignored and because of the number of these cars, it can not be assumed that any road that will carry the heavy traffic is sufficient for the passenger car. This thought, too, was carried through the day, especially in the questions of traffic control, maintenance of highways and the necessity for a close study of maintenance. Chapin's point that too much

is being spent on the maintenance of the vehicle because not enough is spent on the maintenance of the highways was accepted by the highway men.

The only prepared paper of the day, read by Hatt, set forth a tentative plan for the Highway Research Committee, Division of Engineering of the National Research Council. This paper consisted chiefly of questions which the Committee has set out to answer and was illustrated by a chart. It will be printed in an early issue of AUTOMOTIVE INDUSTRIES.

Pride and Estabrook were responsible for injecting some surprising figures into the discussion. Estabrook said that recently the Bureau of Markets and Crop Estimates had determined that 134,400,000 tons of farm produce had moved to market over railways. All of this had, of course, first been transported over the highway. To this must be added produce that is consumed at the end of its highway journey without being handled by the railroad. He had no figures as to manufactured articles that entered into highway transport.

#### Effect of Highway on Truck Maintenance

Pride said that the 990,000 commercial vehicles in service to-day are valued at \$500,000,000 and that the maintenance and depreciation cost of \$3,300,000 annually is entirely too high, due to the fact that the highways are causing much damage. Motor trucking to-day is inefficient and there is much room for improvement. In his later remarks Pride carried this a bit further and said that an enormous cost is being paid by the public because there are so many failures in automotive transport work, due to a lack of proper education of the men who embark in the business. These men, he said, do not know the costs of their work or of maintaining equipment and their consequent failure puts a burden on the trucking industry and adds resistance to the sale of trucks. He strongly favored including a course in cost accounting in any study of motor transport. This view met with general approval. He said that at present there is an annual turnover of something like three billion dollars in this industry and that a study of cost accounting is imperative because of the amount involved. The inefficiency of present trucking, he said, is levying a tax on all commodities. Even the great industrial companies do not know to-day what a factor highway transportation is in the cost of their commodities. It is, he said, an entirely neglected subject.

The subject of administration of highways and highway transport was briefly discussed. Raper favored a State administration, which should be controlled by a national administration to bring about a more uniform plan of maintenance and a better understanding of the factors involved. He spoke of the developments in the work at Syracuse University as showing chiefly the lack of administration understanding.

The problem of personal safety on the highways was discussed by Long and Jennings. The former spoke of the steps now being taken to promote safety through school-room work and through essays. Jennings spoke of the need of a study of individual accidents to determine the cause and the evident failure that awaits the present popular idea that safety can be brought about by the licensing of drivers.

Legislation was only briefly referred to, as this organization has no lobby plans. It merely seeks a basis for the drafting of proper laws. Johnson advocated a course of study of the laws themselves so that the highway transport engineers of the future will be able to advise as to uniformity of laws with understanding. Several of the representatives of other related organizations presented the views of their respective associations on the subject and their offer of aid in legislative matters.

# Bosch Producing a Battery Ignition System

Details of new electrical unit are given in the following description. Timer-distributor is made in two types arranged for automatic or manual advance. Interrupter is designed for high speed operation.

**I**N the past the name Bosch has been associated chiefly with magnetos, but the American Bosch Magneto Corporation has decided to extend its line of products until it meets every electro-mechanical requirement of the motor car industry, and in accordance with this policy a battery ignition system has been brought out. The system comprises two units, the timer-distributor and the coil. The timer-distributor is available in two types, Type T and Type TM. Type T is used with what is known as the compensating battery ignition system, including a governor which through the intermediary of a cam advances the spark in accordance with the engine speed and the particular characteristics of the engine to which the system is fitted. Type TM is without the governor and is hand controlled, but otherwise is identical with Type T. Both systems are provided for 4, 6 and 8 cylinder engines.

The main housing of the timer-distributor, the lower end of which also constitutes the bearing for the timer shaft, is a gray iron casting, machined to receive the interrupter cup which rests in the upper section. In

Type T the shell has sufficient depth to accommodate the governor mechanism. Spring clips hold the distributor cap in place, and permit ready inspection of the interrupter, condenser and distributor. When electric sparks occur for a considerable length of time in an enclosed space, nitric acid is formed, and ventilation is therefore necessary. In this particular instrument the ventilation is accomplished by using tubular rivets for the spring clips.

The timing arm is a drop forging and is mounted on a shoulder at the base of the main housing. It can be clamped in any angular position desired. By moving the main housing, the angular position of the interrupter cup and the distributor cap mounted thereon is changed in relation to the timer shaft and cam around which it moves, thereby advancing or retarding the spark without changing the angular relation of the distributor parts. Manual control may be used in connection with the compensating feature, this being convenient when the engine has to be started by hand cranking, for instance. In the compensating system lubrication of the bearing and governor parts is effected by a simple splash system, the governor ring dipping into oil in a sump in the shell and spraying it all over the interior parts.

The interrupter is assembled in a cup which also contains the condenser, and the whole unit can be easily removed without disturbing its component parts or electrical connections. One of the advantages of the separate cup design for carrying the complete interrupter mechanism within an accurately ground recess in the main housing, is that the device is always assured of a proper position in relation to the supporting walls of the housing, thereby locating it correctly around the cam on the driving shaft. A thumb nut secures the cup in position and, together with the low tension terminal, provides handles for lifting the cup out for inspection purposes.

The interrupter lever is a one-piece steel stamping, copper and nickel plated. It is light but strong and rigid, and only light spring tension is required for its operation. Tests are said to have shown that the interrupter action is perfect even at speeds in excess of 5000 r.p.m. The lever is provided with a bronze bushing which turns on a hardened steel post, insu-

Parts of Bosch battery ignition system. 1—Ring-type governor for controlling automatic advance. 2—Timer-distributor unit arranged for manual advance. 3—Timer-distributor containing automatic advance mechanism. 4—Interrupter mechanism. 5—Coil parts.

lated by means of a micarta plate. The interrupter is provided with a tinned copper shunt which, because of its lower electrical resistance, carries practically all the current, thereby obviating detrimental effects on the interrupter lever spring.

The condenser is of the dry-wound type, fully enclosed and sealed in a moisture-proof metal housing. It is located in the interrupter cup, and connected directly across the contact points.

The governor is of the "tilting ring" type, and, together with the interrupter cam and rotor, is carried on the timer shaft. The range of ignition advance is determined by an advance control stud integral with the governor mechanism.

As the timer shaft rotates, the tilting movement of the governor ring, due to centrifugal force, advances the interrupter cam, which is assembled to the timer shaft in the form of a sleeve, by direct engagement of a stud projecting into a slot provided in this sleeve. The total throw of the governor ring is adjusted by means of stop pins. Tilting of the ring is opposed by an adjustable spirally wound spring located in a recess in the bearing hub of the ring.

For the same general shape of characteristic curve, that is, the same percentage of movement at definite speeds, a total advance of from 0 to 60 deg. can be secured, measured on the engine flywheel. The advance may have a straight line characteristic or its characteristic may curve considerably. Changes in the characteristic of the advance may be brought about by means of stops for varying the range of travel of the ring, by varying the stiffness of the spring, by varying the initial setting of the spring and by changing the radius of the crankpin movement.

The distributor rotor, which is mounted on a projection of the cam and rotates with it, is provided with a skirt to protect the breaker mechanism. The rotor electrode is fastened by a screw into a recess on top,

and is therefore removable. By reason of this method of attachment to the cam shaft, the rotor cannot be replaced incorrectly if removed for inspection. The distributor cap is mounted on top of the main housing, and is brought into alignment with the cam shaft by a slight projection of the interrupter cup over which it fits. A molded-in tongue fits into a slight recess in the housing, which prevents incorrect assembly.

The ignition coil is of the dry-assembly type, as distinguished from coils which are sealed with insulating compounds. Its construction insures accessibility of all parts. It is mounted separately, preferably on the engine side of the instrument board. The core is laminated and permits the insertion of the center bolt holding the different units together. The soft iron band, together with the soft iron end plates, forms a shield for the magnetic circuit against the weakening effect of neighboring bodies of iron or steel, which is said to materially increase the spark energy. The high tension cable terminal is mounted in the center of the tubular casing surrounding the coil, and can be adjusted to any angular position by loosening the center bolt and swinging this casing to the position desired. This was made possible by connecting one end of the secondary to the magnetic shield surrounding the coil, and by providing a spring contact on the cable terminal inside the coil case.

The same coil is used in connection with 4, 6 and 8 cylinder timer-distributors and operates on 6 to 12 volt systems—the only change necessary being to select the proper ballast coil, there being one for six volts and one for twelve volts. The ballast coil (or resistance unit) is electrically connected in series with the primary winding. It protects the coil from burning out in case the engine is left with the battery switch in the "on" position with the interrupter contacts closed, and it also tends to produce a more uniform spark at different engine speeds.

## Two British Developments for Car Applications

### Constant Tappet Clearance

**T**O overcome the tendency of valve clearances to be varied by the unequal expansion which occurs in overhead valve engines, particularly in those having air-cooled or aluminum cylinders, the compensating gear illustrated herewith has been introduced in England. The action of the device provides a canceling motion, which keeps the tappet clearance unaltered. The valve rockers, A, instead of having their pivots mounted on a column directly attached to the cylinder head, are pivoted to a compensating lever, C, which, in turn, is pivoted to the column, E, and at the other end is supported by a tie rod, D, connected to the crankcase or cylinder foot.

By suitably proportioning the levers, the extent to which the pivot of the rockers is raised by the increase of cylinder temperature is reduced to the amount necessary to keep the clearance unaltered. The

lever, C, does not add to the reciprocating weight, and the tie rod, D, can, it is claimed, be used to provide tappet adjustment or provision having the same effect.

Constant tappet clearance device

### New One-Way Spring Damper

**A** SPRING damper acting in one direction only, which has recently been introduced in England by Barduff, Limited, has at least the merit of simplicity, as will be seen by the accompanying cut. Inclosed within a casing is a drum attached to the frame by a flanged member. Encircling this drum is a fabric-lined brake which acts in one direction only—namely, to damp out rebound, the upper movement of the axle relative to the frame being unimpeded. The extended lever is, of course, shackled to the axle by a pivoted link; adjustment of the damping effect is provided by nuts respectively above and below the two coil springs, which keep the band in contact with the drum.

One-way spring damper

# The Influence of Various Fuels on Engine Performance

## Part V.

The relation between mixture strength and indicated mean pressure for various fuels, compression ratios and spark timing is shown and the influence of jacket water temperature and heating of charge determined. Efficiency at reduced loads and when using alcohol is also investigated.

By H. R. Ricardo\*

**B**EFORE any serious tests were commenced on the variable compression research engine, Messrs. Tizard and Pye had undertaken an exhaustive investigation into the process of combustion, and had arrived at very definite conclusions, both as to the chemical changes which might be expected to take place, and as to the limits of thermal efficiency resulting therefrom. Subsequent tests on the two research engines, more particularly on the variable compression engine, and on various fuels, have served to confirm the conclusions they arrived at. The close agreement obtained during tests carried out comparatively recently with their figures deduced many months previously, and from purely theoretical reasoning, is very striking. The writer gives here only the barest summary of their conclusions.

The thermal efficiency obtainable with any fuel depends in the first place upon the compression ratio at which it can be burnt, and this in turn is governed by the tendency of the fuel to detonate under high compression pressures. At any given compression ratio the thermal efficiency is dependent upon the maximum temperature. Upon flame temperature depends also the direct loss of heat to the cylinder walls, the loss due to dissociation, and that due to increase in the specific heat of the working fluid at high temperatures. The maximum temperature is dependent upon the mixture strength and the available internal energy of the fuel.

The whole question of the extent and influence of dissociation and the change in specific heat at high temperatures was dealt with very thoroughly by Messrs. Tizard and Pye. Broadly speaking, the results of their theoretical investigations have been to indicate:

(1) That when both change in specific heat and dissociation are taken into account the maximum temperature obtained with economical mixture strengths is substantially the same in the case of all available hydrocarbon fuels, though it is perceptibly lower in the case of alcohol.

(2) That the gain in efficiency with increase in compression ratio is very considerably greater than would be predicted from the air cycle formula.

(3) That the theoretical thermal efficiency for the most economical mixture strength may be expressed by the formula  $E = 1 - \left(\frac{1}{r}\right)^{0.78}$ .

This formula takes into account both change of specific heat and the effect of dissociation, and represents

the ideal efficiency obtainable from a working fluid consisting of air and any volatile hydrocarbon fuel, assuming complete combustion (within the limits imposed by dissociation) and no loss of heat to the cylinder walls.

In Fig. 15 are shown three curves: (a) the air cycle efficiency for a range of compression ratio from 4:1 to 7.5:1; (b) Tizard and Pye's ideal thermal efficiency corresponding to the same range of compression, and (c) the observed results on the variable compression engine with most economical mixture strength based on the net calorific value of the fuel and including the latent heat of evaporation. It will be observed that throughout the whole range the relation between the experimental results and the calculated ideal efficiency is constant to within very narrow limits. The difference between the two represents the heat loss to the cylinder walls during combustion and expansion, and the small loss due to the early opening of the exhaust valves. All the tests showed that the gain in efficiency with increase in compression was almost exactly the same in the case of all fuels tested. Naturally, the majority of the fuels would not stand so high a compression ratio as 7.5:1 without detonation or pre-ignition, but up to the highest useful compression for each fuel the curves of efficiency plotted against compression ratio were almost coincident in all cases. Alcohol, for reasons which will be dealt with later, gave a higher thermal efficiency throughout the range of compression, though the curve showed practically the same proportional variation.

The determination of the true absolute thermal efficiency obtainable from different fuels has proved somewhat difficult. Such a determination pre-supposes an accurate knowledge of the effective calorific value of the fuel, and it is in acquiring this that the principal difficulty lies. Much of the published data is clearly unreliable, and must be discarded, while in many cases the very precision with which the calorific value is given to four, or even five, places is sufficient to engender suspicion in view of the great difficulty in the way of making an accurate determination. In regard to the application of the calorific values, as determined, to the calculation of engine thermal efficiency, there is a factor which does not appear to have been taken into consideration in previous investigations on this subject. This factor is the influence of the latent heat of evaporation upon the evaluation of the useful calorific value.

When a sample of liquid fuel is tested either in a Junkers or a bomb calorimeter, some at least of the heat liberated during combustion is devoted to overcoming the latent heat of evaporation of the liquid. In the case

\*From a preliminary report (slightly condensed) on research work conducted by the author and other investigators for the Asiatic Petroleum Co. and published in the Automobile Engineer.

Fig. 15—Relation between thermal efficiency and compression ratio. Fig. 16—Relation between fuel consumption and indicated mean pressure with three different fuels, all used with 5 to 1 compression ratio. Fig. 17—Relation between fuel consumption and indicated mean pressure with benzol at different compression ratios

of the bomb calorimeter, for example, when a sample of liquid fuel is placed in the bomb only a trifling proportion is evaporated before combustion commences. During the process of combustion the remainder of the fuel is evaporated, and the heat required for overcoming the latent heat of evaporation is supplied by combustion. Now when used in an engine the whole, or very nearly the whole, of the fuel is evaporated before the end of the compression stroke, such small proportion as escapes evaporation usually passes through the cylinder unburnt. In practice the proportion of liquid fuel which actually both evaporates and burns during the combustion stroke may be considered as negligible, so that the heat required for evaporation may be regarded as being supplied either outside the cylinder or at least outside the heat cycle. It has been fully accepted by engineers that the latent heat of evaporation of the water formed by the combustion of any hydrocarbon and air should be deducted from the total available heat, because, owing to the high temperature of the cycle, no water is condensed, and consequently this heat cannot be made use of. It is therefore proper and customary to subtract from the total heat the heat equivalent of the evaporation of the water formed. It appears also to be right and proper to add to the total available heat the latent heat of evaporation of the fuel, since this is supplied outside the cycle. To be more strictly accurate there should be added the latent heat at constant volume, which is less than the latent heat at constant pressure by the amount of the work done on the atmosphere if the liquid is vaporized when uninclosed. So far as ordinary gasolines are concerned, the latent heat of evaporation of the fuel bears but a small proportion to its total heat, and does not seriously affect the issue; but in the case of the alcohol group its proportion becomes a very considerable one and should most certainly be taken into account. The most reliable determinations of the calorific value of alcohol, at present available, do not take into account the latent heat of evaporation, and the very high apparent thermal efficiency obtainable with this fuel is therefore largely fictitious.

Theoretical considerations would lead one to suppose that the thermal efficiency, that is to say, the proportion of the total effective heat converted into useful work, should be substantially the same at the same compres-

sion ratio for all fuels, with the possible exception of the members of the alcohol group. This is fully borne out by the experiments made. Provided the fuel is vaporized, or that all liquid is sufficiently finely divided and in suspension, the thermal efficiency at any compression ratio is practically constant.

In Table IX the following values are given for each fuel:

Column B.—The lower calorific value according to the accepted standards and the most careful and reliable determinations.

Column C.—The minimum fuel consumption in lb. per I.H.P. hour actually observed with a compression ratio of 5:1 and standard heat input to the carbureter.

Column F.—The "lower" calorific value (Column B) plus the latent heat of evaporation at constant volume.

For all the data given in these articles, except where specifically mentioned, the thermal efficiency has been calculated from the corrected calorific value of the fuel as given in Column F of Table IX, i.e., the calorific value as determined by bomb calorimeter minus the latent heat of evaporation of the water formed, but plus the latent heat of evaporation of the fuel at constant volume.

In the case of the special research engines, the means provided for measuring both the power output and the fuel consumption were such as to insure an accuracy (based on the mean results) of about  $\pm 0.25$  per cent.

It is very doubtful whether the useful calorific of a composite fuel such as gasoline can be ascertained to within closer limits than  $\pm 0.5$  per cent, more particularly when the fuel used is not a chemically pure substance, so that the observed heat value cannot be checked by analysis.

In all tests for power output and efficiency the following procedure was invariably adopted. The engine was run up to speed; the necessary adjustments were made, and a check test was taken on the standard fuel. So soon as the behavior of the engine was ascertained to be entirely normal the fuel was changed, without stopping the engine, to the sample to be examined. The needle valve in the carbureter was then opened until the power output fell slightly, due to over-richness of the mixture and readings of torque, speed and consumption were commenced. The standard jacket temperature, namely, 60 deg. C. (140 deg. Fahr.), and the standard rate of

heat input to the carbureter, namely, 0.0433 B.t.u. per min. per r.p.m. was maintained throughout the test by means of adjustment for each change of mixture strength. The exact number of revolutions during the consumption of a given quantity of fuel was recorded automatically by means of the magnetically operated counter. After each reading the needle valve in the carbureter was closed very slightly, and, after all temperatures had become re-settled, another reading, both of power output and fuel consumption, was taken. This procedure was repeated continuously until the mixture strength became too weak for steady running. Over-weakness was generally indicated first by a tendency to hunt, followed by popping back into the carbureter if the mixture were still further weakened. Such tests were carried out on every sample of fuel examined, and when the quantity available permitted, similar tests were run at different speeds, different jacket temperatures, or different rates of heat input to the carbureter. The results obtained from three of such tests are shown in Fig. 16, giving fuel consumption plotted against the mean pressure for gasoline "A," pure benzol, and for ethyl alcohol 98.5 per cent at a compression ratio of 5:1. Fig. 17 shows similar curves for benzol at different compression ratios, namely, 4, 5, 6 and 7 to 1. It will be seen that the general form and character of the curves so obtained are substantially the same for all the fuels. The differences that do occur are of a small order except in the case of the alcohol group. In the case of alcohol the power continues to rise with increase of mixture strength to an important extent. This is quite certainly due to the increased volumetric efficiency with rich mixtures resulting from the high latent heat of the fuel and the consequent fall in temperature of the charge. The relation between power output and consumption on the weak side is substantially the same for all fuels, but on this side

the efficiency obtained depends to a greater extent upon the nature and intensity of the ignition spark and upon its timing. Tests on the weak side were run, both with the ignition set to give maximum efficiency at normal mixture and with the ignition adjusted to suit each reduction in mixture strength. Fig. 18 shows the curves obtained (a) with fixed ignition setting, (b) with the setting adjusted for each change in mixture strength. It was observed that the ignition required to give maximum power on any gasoline with a compression ratio just below its detonation point and between the limits 4.5 to 5.5:1 was 31 deg. before top center at 1500 r.p.m. The ignition could be advanced with advantage when working on the weak side to as much as 45 deg. early on the weakest mixtures. The same applies in the case of all fuels tested. It is interesting also to note that at about the mixture strength giving complete combustion the ignition timing required was very nearly the same for all fuels from heptane to toluene or alcohol.

While the behavior of fuels at mixture strengths weaker than that giving complete combustion is very interesting from a scientific point of view, and highly suggestive of possible developments, yet, so far as the multi-cylinder engine is concerned, it is of but little practical value at present, because, owing to irregularities in distribution, such weak mixtures cannot be used. In every instance where any attempt has been made to supply to a four-cylinder engine a mean mixture strength appreciably weaker than that giving complete combustion, the result has been that one or more cylinders of the group are starved, their ignition becomes irregular, and back firing into the carbureter takes place.

In previous articles when dealing with the subject of detonation, it has been stated that the tendency to detonate is at a maximum at or about the mixture strength giving maximum economy. This is practically, scientific-

\*This sign indicates that at a compression ratio of 5:1 the fuel could not be used owing to detonation. These values for fuel consumption are therefore calculated from the readings obtained from tests made with lower compressions. The close agreement between thermal efficiencies calculated from these results clearly shows the uniformity of the relation between compression ratio and thermal efficiency for the different fuels tested.

†The low thermal efficiency observed for those fuels is quite certainly due to non-combustion of a portion of the fuel which probably remains liquid during the working stroke.

‡The calculated heat value for methylated spirits was given in Part I of these articles as 9,850 under a misapprehension as to the water content. The value now given, namely, 10,200 B.t.u. per lb., is probably nearly correct for the ordinary purple variety of this specific gravity.

ally true. Strictly speaking, the tendency to detonate is at a maximum at or about the mixture strength giving complete combustion, and this in practice is almost coincident with that giving maximum economy. With the very weak mixtures a rather higher compression can be used without detonation, but under such a condition an engine is working between exceedingly narrow limits of mixture strength. Satisfactory running would be quite unattainable with an ordinary carburetor even on a single-cylinder engine. In any multi-cylinder engine to work within such limits of mixture strength is certainly far outside practical possibility. With a view to investigating this point more thoroughly a careful series of tests was made on the standard aromatic free gasoline over a range of mixture strengths from 75 per cent rich to 25 per cent weak. After each adjustment of mixture strength the compression ratio was varied so that detonation was just audible. The results of this interesting test are shown in the curves, Fig. 19. It will be seen that with any mixture strength between 10 per cent rich to 10 per cent weak the available compression ratio was 4.85:1. When the mixture was varied in either direction beyond these limits it became possible to raise the compression without causing detonation. The full line curve shows that when the mixture was 20 per cent weak the compression could be raised to 4.95:1, and with a mixture strength 75 per cent rich the compression could be increased to 5.75:1. The ignition setting was adjusted

to give maximum power for each condition. In the same figure is shown (a) the variation in m.e.p. over the same range of mixture strength at a constant compression ratio of 4.85:1, and with ignition timing adjusted to suit each mixture strength; and (b) the same again, but with compression ratio adjusted as permitted by each change of mixture strength. From these curves it will be seen that only a very slight increase in compression ratio can be obtained with weak mixtures, and then only when the mixture is so weak that the running is become unstable.

#### Influence of Jacket Water Temperature

While all standard tests were run with a jacket water temperature of 60 deg. C. (140 deg. Fahr.), some series of tests were also run at temperatures of 35 deg. C. (95 deg. Fahr.) and 85 deg. C. (185 deg. Fahr.). In the case of all fuels boiling below about 180 deg. C. (356 deg. Fahr.) the water temperatures did not influence the efficiency to any appreciable extent, though in some cases, notably with the more volatile fuels, a very slight gain in efficiency was observed when the water temperature was at its lowest, due probably to the general reduction in the temperature of the cycle. The difference was, however, exceedingly small, and for all practical purposes may be regarded as insignificant. It must be understood that these remarks refer to the indicated thermal efficiency. So far as the brake thermal efficiency is concerned, any increase in temperature of the cylinder

Fig. 20—Effect of heating the charge on the relation between fuel consumption and indicated mean pressure.

walls results in a decrease in piston friction due to the lower viscosity of the lubricating oil. The gain in mechanical efficiency due to reduced friction losses with higher jacket temperatures generally more than outweighs any difference in indicated thermal efficiency. Since piston friction is purely a mechanical factor and varies widely in different engines, it is thought best to deal only with the indicated performance. In both the variable compression and the supercharging engines on which these tests were made the piston friction is so low that the brake thermal efficiency was virtually unaffected by changes in the temperature of the cooling water.

#### Influence of Heat Input to the Carbureter

In all the standard tests a uniform rate of heat input of 0.0433 B.t.u. per minute per r.p.m., or 65 B.t.u. per minute at 1500 r.p.m., was supplied. Other series were also made with no heat input to the carbureter, and also with a heat input of 0.066 B.t.u. per minute r.p.m.

So far as the more volatile fuels are concerned, that is, fuels boiling below 180 deg. C. (356 deg. Fahr.), the heat input, while affecting the power very adversely by reducing the weight of charge entering the cylinder, had no influence upon the thermal efficiency except in so far as a high rate of heat increased the tendency to detonate, and so necessitated the use of a lower compression ratio. The effect of heat input to the carbureter and of water jacket temperature when running with a mixed fuel having an abnormally wide range of boiling, will be dealt with later, but the above remarks must be regarded as applicable to reasonably volatile and homogeneous fuels such as the various gasolines given in the tables, also the lighter aromatics and naphthenes. In the case of 95 volume per cent ethyl alcohol the efficiency rose from 31.6 per cent to 32.5 per cent, when the heat input was raised from nil to 0.066 B.t.u. per minute per r.p.m. In view of the behavior of most of the gasolines which have very much higher final boiling points, this feature is perhaps a little curious; but alcohol, owing to its higher latent heat, its considerable water content, and its low vapor tension, behaves somewhat differently from most of the other fuels tested. Fig. 20 shows the M.E.P. and fuel consumption obtained with 95 volume per cent ethyl alcohol, curve (a) with no heat input, and curve (b) with a heat input of 0.066 B.t.u. per minute per r.p.m. It will be seen from these curves that the minimum fuel consumption is appreciably lower under the heated condition. The maximum power output, of course, is very much lower. From tests on multiple-cylinder engines on gasoline, benzol, etc., where the problem of distribution enters into the account, it was found that a very considerable heat input was required in order to obtain the best thermal efficiency. The heat required varied con-

siderably for different engines; the amount may be taken as an inverse measure of the efficiency or otherwise of the distribution system.

#### Efficiency on Reduced Loads

When the load on an engine is reduced by throttling the supply of working fluid, and the mixture strength is maintained the same as for full load, the temperatures in the heat cycle will be substantially the same, since neither the ratio of compression nor the heat of combustion of the mixture are altered. The only condition which is changed appreciably is the proportion which the residual exhaust products bear to the whole of the working fluid. Apart from the latter consideration the efficiency of the cycle should remain very nearly the same at all throttle openings. Experiments with the time of ignition fixed at that giving maximum efficiency on full throttle have shown that, as the throttle is closed and the power output is reduced at constant speed and constant mixture strength, the efficiency falls; but when the ignition is readjusted to give maximum efficiency at each throttle opening, the indicated thermal efficiency remains substantially constant over a wide range of load, e.g., from 40 per cent to 100 per cent. Fig. 21 shows (a) the indicated thermal efficiency observed on petrol with a constant mixture strength and fixed ignition setting, and (b) the indicated thermal efficiency with the ignition adjusted at each load to give maximum efficiency. It will be observed in the case of curve (b) that the efficiency at about 70 per cent full load is actually appreciably greater than that obtainable on full loads. This characteristic is not peculiar to gasoline, but has been observed also with alcohol. Very great care was taken to ascertain carefully the variation in pumping losses at the different throttle openings, and to correct for such variation when computing the indicated power or efficiency. It would appear that the presence of a greater proportion of exhaust products on reduced loads influences appreciably the rate of burning of the mixture, and therefore necessitates an earlier ignition timing.

Fig. 22 shows the variation in heat distribution for gasoline "A" with different loads at a constant speed of 1500 r.p.m. and under uniform conditions as to heat input, jacket temperature, etc.

Fig. 23 shows a similar set of curves for 95 volume per cent alcohol under identical conditions. In both cases the heat input to the carbureter was proportional to the load and equivalent to 65 B.t.u. per minute at full load.

#### Efficiency on Alcohol

While at any given compression ratio the thermal efficiency was found to be the same on all volatile hydrocarbon fuels, the efficiency obtained with alcohol was consistently higher. For the samples of ethyl alcohol and for a sample of methylic alcohol (purified wood naphtha) accurate calorific values were obtained. These determinations were made by The Asiatic Petroleum Co. at their central testing laboratory at Shell Haven. The determination made of the heat value of 98.5 per cent ethyl alcohol agreed with the value given by Richards to within 0.25 per cent. The values for the alcohol are given in Columns B and F of Table IX. Very careful tests were run with 95 volume per cent ethyl alcohol at compression ratios of 3.8:1, 5:1 and 7:1 under exactly similar conditions as to speed, jacket temperature and rate of heat input to the carbureter. The distribution of heat to the jackets and to the exhaust was very carefully determined also. Similar tests were run also on several gasolines (within the limits of useful compres-

sion ratio) and on benzol. The results obtained are shown in Table X.

TABLE X

A	B	C	D	E
Com- pression Ratio	Ind. Therm. Efficiency, Alcohol 95 Vol. %	Ind. Therm. Efficiency, Hydro- Carbons	Relative Efficiency, Alcohol 95 Vol. %	Relative Efficiency, Hydro- Carbons
3.8:1	26.8	26.3	65.0	63.7
5.0:1	32.5	31.7	68.5	66.8
7.0:1	38.2	37.4	70.7	69.3

From this table it will be observed that the thermal efficiency obtained with ethyl alcohol at all compression ratios was some 2½ per cent higher than that obtainable with hydrocarbon fuels, when the calorific values in all cases are subjected to the same corrections for the latent heat of evaporation. The explanation of this gain in efficiency is to be found in the reduction in the temperature of the cycle due to the evaporation of the alcohol within the cylinder. In all cases the heat input to the carbureter at 1500 r.p.m. was at the rate of 65 B.t.u. per minute.

TABLE XI

Fuel	Total Heat of Fuel, B.t.u. per Hr.	Heat to I.h.p., B.t.u. per Hr.	Heat to Jacket Water, B.t.u. per Hr.	Heat to Exhaust, Etc., B.t.u. per Hr.
Gasoline	253,000	66,800	72,400	113,800
Alcohol, 95 vol. %	275,000	73,900	67,200	133,900

In the last article it was shown that the drop in temperature of the working fluid due to the evaporation of the liquid fuel was, in the case of gasoline "A," 20 deg. C. (68 deg. Fahr.), and in the case of ethyl alcohol 98 per cent., 85 deg. C. (185 deg. Fahr.), while in the case of 95 per cent volume it would, owing to the high water content, be equivalent to 97 deg. C. (207 deg. Fahr.). There appears to be no doubt that practically the whole of the fuel and the water contained in it evaporates completely either during entry to the cylinder, or, at any rate, before the completion of the compression stroke; it is clear, therefore, that the temperature at the end of compression will, in the case of alcohol, be some 70 deg. C. (158 deg. Fahr.) lower than in the case of gasoline. Since the maximum flame temperature of an alcohol

mixture is also about 100 deg. C (212 deg. Fahr.) less than that of a gasoline mixture, it follows that in the former case the highest flame temperature attained will be approximately 170 deg. C (338 deg. Fahr.) lower than that of a gasoline mixture, and the loss of heat to the jackets and that due to change of specific heat, etc., will be substantially reduced. Again, when running with alcohol, the total weight of working fluid passing through the cylinder is greater as explained previously, hence the relative loss of heat will be even slightly less than would appear from a consideration of the temperatures alone.

Table XI shows the heat distribution observed when running with gasoline "A" and with 95 volume per cent ethyl alcohol with a compression ratio, in this instance, of 3.8:1. The mixture strength both for the gasoline and for the alcohol was that giving maximum efficiency. From a comparison of the proportionate heat loss to the cylinder cooling water, it will be observed that the amount of heat given up to the cylinder walls is considerably greater in the case of gasoline than alcohol, indicating again a considerably higher cycle temperature.

Figs. 24 and 25 show respectively the observed variation in the distribution of heat (to indicated work, to cooling water, and to exhaust) with different mixture strengths on gasoline and alcohol in both cases at a compression ratio of 5.45:1. The horizontal scale denotes the total number of B.t.u. per hour supplied to the engine, and the vertical scale the percentage accounted for in i.h.p. and cooling water. The upper curve is plotted by difference, and represents the heat rejected in the exhaust and by radiation.

Table IX gives the observed minimum fuel consumptions in lb. and in pints per indicated horsepower hour. Columns H and I show the consumptions for a fixed compression ratio of 5:1. Columns J and K give the minimum fuel consumption obtained when running the engine with the highest useful compression ratio for each fuel.

## Strength of Screw Fastenings in Plywood

IF the screw fastenings in plywood construction are to be as strong as the plywood itself, it is important to adapt the size of screw, spacing, and margin to the particular species and thickness of plywood used. Tests made at the Forest Products Laboratory have shown that the commonly-used plywood species may be divided into the following groups, all woods in any one group requiring the same screw fastening to develop maximum strength.

GROUP I—Low Density		
Basswood	Douglas fir	Pine, white
Cedar, Spanish	Fir, true	Poplar, yellow
Cottonwood	Hemlock	Redwood
Cypress, bald	Pine, sugar	Spruce, Sitka
GROUP II—Medium Density		
Ash, black	Gum, cotton	Mahogany
Ash, pumpkin	Gum, red	Maple, soft
Elm, white	Hackberry	Sycamore
Gum, black	Magnolia	Walnut, black
GROUP III—High Density		
Ash, white	Birch	Elm, cork
Beech	Cherry, black	Maple, hard

The screw sizes, margin, and spacing for use with each species and plywood thickness will be found in the following table. The gage is the smallest that can be used with the thickness specified and not cause failure through breaking of the screw when the full strength of the plywood is developed. The length of screw is the shortest which will prevent the screw from pulling out before the full plywood strength is reached. The margin is the

smallest distance from edge of hole to edge of plywood which will insure against failure by shear. The spacing is the distance from center to center of screw holes which gave maximum strength per linear inch.

SIZE AND SPACING OF SCREWS FOR MAXIMUM STRENGTH IN PLYWOOD

Species of Plywood	Thick- ness of Plywood in Inches	Gage (Num- ber) of Screw	Screw Length in Inches, Species Receiving Point		Margin in Inches	Spacing in Inches
			White Ash	Spruce		
Group I	3/30	4	1½	¾	1½	¾
	3/24	5	1½	¾	¾	1½
	3/20	6	¾	¾	¾	1½
	3/16	7	¾	¾	¾	¾
	3/10	9	¾	1	¾	¾
	3/8	11	1	1½	¾	¾
Group II	3/30	5	1½	¾	1½	1½
	3/24	6	¾	¾	¾	1½
	3/20	7	¾	¾	¾	¾
	3/16	8	¾	1	¾	¾
	3/10	10	1	1½	¾	¾
	3/8	12	1½	1½	¾	¾
Group III	3/30	6	¾	¾	1½	1½
	3/24	7	¾	1	¾	¾
	3/20	8	1	1½	¾	¾
	3/16	9	1½	1½	¾	¾
	3/10	11	1½	1½	¾	¾
	3/8	13	1¾	2	¾	1

About equally good results were obtained with flat-headed screws without washers and round-headed screws with washers. Round-headed screws without washers proved an inferior means of fastening. The spacing given in the table is for screws in a single row, but staggering is recommended wherever possible.

# The Specification and Testing of Castings

Every engineer is aware of the difficulty of satisfactorily testing castings. Various methods are used, but each is subject to certain defects. Dr. Rosenhain analyzes here the different methods, points out their merits and deficiencies, and indicates the best practice under present conditions.

By Dr. Walter Rosenhain, F.R.S.

**C**ASTINGS play an important part in all automobile construction and it is correspondingly important that satisfactory methods of making tests and drawing up specifications should be arrived at. Yet there can be no doubt that it is a much more difficult matter to deal with castings in this respect than with other materials of construction. The reason is that the physical properties of metal which has undergone forging and rolling operations are rendered, to a considerable extent, uniform thereby, minor inequalities which may have existed in the ingot or slab being more or less "smoothed out."

It is true, of course, that no amount of hot or cold working will make really sound metal out of an unsound or segregated ingot, but enough is known about the nature of ingots or slabs to make it possible, by reasonable supervision, coupled with sound practice, to eliminate the grosser defects and differences, and minor differences only affect the properties of the final wrought product to a secondary degree.

It is quite different with an actual casting. In nearly all metals the physical properties depend to a very large extent upon the rate of solidification and cooling, so that the temperature of the metal at the time of pouring the casting, the temperature (or dryness) of the mold and its heat capacity, as well as the mass of the casting or of any particular portion of it, all affect the properties of the resulting piece. There are other factors also—dependent upon the design of the casting and the manner in which it is molded—which bring with them differences in the degree of soundness in different parts of the same casting. Taking all these factors together, it would seem that it is no easy or simple matter to state what is the "strength" of a given casting, even when the conditions under which it is made are carefully considered.

Some experiments to test this point have been carried out under the auspices of the British Aircraft Inspection Directorate of the Air Ministry, who took several crank-cases cast in aluminum alloys for aeroplane engines, cut them up and prepared a number of test pieces from various parts of the same casting so as to represent portions of varying thickness. Very great variations in tensile strength were found; as a rule, test pieces cut from the thinner portions proved to be much stronger than those cut from the thicker portions, but the relative position in the casting of the test piece and the "gates" and "risers" was also of importance. It may be that these differences are particularly well marked in aluminum alloys, but there is every reason to believe that the same results would be obtained with castings made of other metals. Further, if in a sand-casting, for instance, local chills were introduced with a view to affecting the rates of cooling of different portions, the effect on the resulting

tensile properties of test pieces cut from various portions of the casting would be still more marked.

If we face the facts squarely, then, we must admit that the material of any given casting does not possess any definite "strength" or even "tensile strength." How, then, are we to test our castings and how specify their strength? Various methods have been adopted and are more or less strongly advocated, and it will be worth while to examine them somewhat closely in order to arrive at a reasoned answer to our question.

## Testing Whole Casting

An obvious first suggestion is to test the casting as a whole in some well-defined manner, much in the way in which a railway tire is tested by placing it under the drop-hammer. With castings of complex shape, however, this is a difficult matter. It is, first of all, rarely possible to carry out such a test except under compression, and the compression properties of a casting are by no means necessarily representative of its tensile properties or of its "strength" generally.

Then, too, there is the difficulty of securing any reasonable degree of accuracy in a test upon a body of irregular shape. Slight variations in the position of the casting during the test, and, still more, slight variations in the thickness of the casting at the most heavily stressed point, are liable to bring with them variations greater than those which would normally be found as between a "good" and a "bad" casting of the same nominal metal.

Indeed, were the method of testing in this way once specified, it would be quite an easy matter for the founder—if he so wished—to thicken the casting slightly in the right place in such a way as to make it stand up to that particular test. Since the test can scarcely be made to correspond to real service conditions, the result might be anything but satisfactory so far as the real usefulness of the casting is concerned.

## Test Pieces and Bars

The next method to be discussed is one which has been widely used for certain purposes; it consists in making tests on test pieces cut out of definite places in actual castings. It shares with the previous method the serious disadvantage that a certain number of apparently good castings are destroyed for testing purposes, and, where large and complicated castings are concerned, this would be a serious matter. Nor is the cost of such a proceeding counterbalanced by any real advantage. If the portion of the casting to be used for the test is specified beforehand, it is a comparatively easy matter for the foundryman to make sure that this particular portion of the casting is entirely satisfactory. Quite apart from difficulties of that kind, however, such a test piece will

not, in the ordinary way, be truly representative of the casting as a whole; it may show too high or too low a strength, according to the kind of part from which it has been cut.

The third and most widely used and advocated method consists in specifying that one or more "test bars" shall be molded along with the casting and connected to it in a suitable runner, so that these bars are cast together with the main casting. The advocates of this method suggest that in such "cast on" test bars we have, substantially, a portion of the main casting itself, cast under the same conditions and in the same kind of mold, but always of a standard thickness, so that the effects of variations in the rate of cooling do not occur. This looks satisfactory at first sight, but there are difficulties about it.

The first of these is that there is no certainty whatever that the bars are really cast under the same conditions as the main castings. It is true that they are poured with the same metal and at the same temperature. On the other hand, the founder, in his own interests, will and must take care that these bars turn out as sound and strong as possible, and it does not follow, therefore, that the conditions of feeding, etc., will be the same for the test bars as for the casting to which they are attached.

Cases have been known where the test bars were so placed that during solidification the test bars were fed by metal drawn from the rest of the casting, which thus actually suffered "drawing" for their benefit. Nor need such an occurrence be the result of any intentional action on the part of the founder; it may easily occur without his knowledge or desire, and it is not, therefore, to be regarded as a difficulty of the same order as that which would arise if the test bars were "helped" by the insertion of suitable chills into the mold. Yet even if all these pitfalls be avoided, the "cast on" test bar is not a true index of the strength of any part of the casting itself, since the effects of drawing, contraction stresses, etc., are all more or less completely eliminated in the case of the bars, while they play a most important part in the main casting.

### Determining Metal Quality

If we feel obliged to admit the force of these destructive criticisms of the three methods of testing castings which we have so far discussed, what possibility remains open to us? The answer is that, although it is more or less futile to endeavor to obtain tests representing the strength of actual castings, it is possible and desirable to obtain tests representative of the quality of the metal of which the casting has been made.

If we are satisfied that the metal was right in composition, temperature, etc., and inspection shows that the casting is a good one—sound and free from "drawing"—then we can be sure that the strength of the casting will be as good as the material in question can yield. If one thinks of it carefully, no test can really establish more than this, unless it is one which can be applied to every casting without causing destruction. Our problem, then, resolves itself into devising a means whereby the quality and condition of the metal from which any casting has been poured can be satisfactorily tested. This is a relatively simple problem, since it is only necessary to have a sample of the metal poured into some standard mold immediately before and, preferably, also immediately after the main casting is poured.

It may perhaps be urged that the "cast on" test bar constitutes the simplest and safest way of doing this, but certain objections to the "cast on" bar have already been mentioned. Beyond these, however, there is this

very serious one, that "cast on" bars have nearly always to be cast in a sand mold, and it is by no means easy to standardize a sand mold to a satisfactory extent. Small differences of ramming, venting, gating, etc., make large differences to the resulting bar. All these objections are removed if the test bars are cast in separate small chill molds. These can easily be made and kept to a closely defined standard, nor can they be in any way tampered with or altered in such a way as to give a "better" result than the metal deserves.

These considerations do not, perhaps, apply to cast iron, in which material a chill cast bar would obviously be quite unsuited for testing and entirely out of relation with any casting molded in sand. For other metals, however, and particularly for aluminum alloy castings, with which the automobile engineer is deeply concerned, it may safely be said that the results obtained with a bar cast in a chill mold 1 in. in diameter and from 9 to 12 in. high are a good approximation to the best results which can be obtained from cast material without heat-treatment.

### Weakness of Test Bar Method

It is this very consideration, that the separately cast chill test bar gives the best value obtainable with the alloy, which is both the great strength and—in one sense—the weakness of this method of testing and specifying the strength of cast material. Its strength lies, as already indicated, in its easy standardization and in the practical impossibility of improving, by any ordinary device, upon the results which the straightforward use of the chill will give.

The test thus furnishes the clearest and most definite measure of the quality of the actual material used in the production of the casting. The weakness of the method—such as it is—lies in the fact that the strength found in the chill-cast test bar is not even approximately the same as that of the actual casting. It is sometimes suggested that the appearance, in the specification, of the high tensile test figure which the chill-cast test piece must produce is apt to mislead the designer and to give him the impression that the material is much stronger than is in reality the case. This is, surely, an aspersion on the intelligence of the designer, who must know enough of his materials to appreciate the difference between a standard chilled bar and the various portions of a casting molded in sand, with or without the introduction of local chills.

Provided that such unintelligent misinterpretation of specifications need not be considered seriously, the value of the test figure from a chill-cast test piece is at least as great as that from any other test piece that can be used. None of them, as we have seen, can be taken by itself to represent the real strength of the casting, and the only sound method of handling the problem is to correlate the actual strengths found by a few preliminary tests on pieces cut from various parts of a casting with the results of a standardized test made upon the metal at the same time. Once such correlation has been obtained, and provided that the inspection of the castings is carefully carried out so as to insure the absence, at least, of visible unsoundness and drawing, then the data obtained from current tests on a standard chill-cast bar can be safely used as a guide to the quality of the metal used and, therefore, of the castings themselves. It is, at all events, a sounder guide than can be obtained from test results of pieces produced in a less standardized and more readily varied manner.

### Accessory Tests

While the whole problem of the testing and specification of castings is thus a difficult one, there are certain

accessory tests which can be usefully employed. These are the ordinary "hardness" tests by means either of the Shore scleroscope or some modification of the Brinell ball-indentation test. By either of these methods it is possible to make tests, if desired, upon definite parts of every single casting.

By itself such a test could scarcely be regarded as adequate, since the correlation between tensile strength and Brinell or scleroscope number is not very reliable in aluminum alloy castings unless very careful control of the chemical composition is at the same time maintained. But as an adjunct to the system of testing by means of standard chill-cast tensile test bars, these hardness tests are particularly valuable. They can be made in such a manner as not to affect the usefulness or the appearance of the casting, and they can be made rapidly and, therefore, cheaply. Their utility lies mainly in serving as a test of uniformity of quality, but correlation with the tensile properties, both of the casting itself and of the test bar, is perfectly possible for any given alloy and type of casting.

Apart from the purely mechanical tests which have been discussed above, a number of other problems arise, particularly in connection with aluminum alloy castings. For certain purposes, particularly pistons and cylinders of engines, porosity is regarded as dangerous and tests are often specified to guard against such a defect. This generally takes the form of a test under hydraulic pressure of moderate severity—200 to 300 lb. per square inch, and the casting is required not to "sweat" under this test. If it does, the question arises whether any form of "stopping" or "doping" shall be permitted. Under war conditions British practice permitted "doping" with solutions of silicate of soda in the case of all castings other than pistons, but it is very doubtful whether such treatment is not unduly risky for other than war purposes. It is certainly a thing to be avoided if at all possible, and recent progress in the casting of aluminum alloys suggests that aluminum foundries should be perfectly

able, under normal conditions, to produce castings which do not require "doping." They may cost a little more—on account of occasional rejections—but the automobile engineer is well justified in insisting upon having them.

While insisting upon having his castings sound, non-porous and free from "drawing," the engineer should not attach undue importance to one feature which is frequently found in aluminum alloy castings. This consists of numerous very small spherical holes which can be seen on most of the machined surfaces of such castings. These appear to be due to very minute gas bubbles liberated at the moment of solidification. If one watches the surface of the molten alloy just prior to solidification, it behaves rather like the surface of very weak soda-water—minute bubbles rise and burst or remain on the surface—there is, indeed, a very mild kind of effervescence. Very great care in melting the metal is required to reduce or eliminate these minute bubbles, but fortunately they do not appear to be seriously harmful. The writer has repeatedly found that test pieces giving exceptionally good results were apparently full of these bubbles, while others, nearly or quite free from them, gave lower results. They are not, of course, a desirable feature, but they do not indicate real porosity and it would be unwise to reject a casting on their account if they are not unduly large.

While the remarks in the last few paragraphs of this article have been devoted specifically to aluminum alloys, most of the general considerations put forward apply to castings in most metals, although cast iron presents problems of its own. Enough has been said, however, to suggest that the specification and testing of castings is a matter which requires careful consideration. Under war conditions it has received this consideration in England, and the method of the separate chill-cast test piece has been adopted very widely. In American practice this is not the case, and for that reason it has, perhaps, been worth while to set forth the whole case, as fairly as possible, here.

## A Four-Valve Motorcycle Engine

**R**ICARDO has designed for the British motorcycle maker with the largest output (Triumph), a four-valve single cylinder engine for use in the recent Isle of Man motorcycle road races. The new engine has the valves in pairs at 90° in a detachable cast iron cylinder head. They are operated by a pair of push rods. A separate pocket and pipe is provided for each exhaust valve, but the inlet valves have a single pipe and port. A machined steel cylinder with horizontal ribs is used and is held to the aluminum crank case by four set screws in steel bushes. The head is secured to the cylinder by four long bolts passing down through the double bottom rib. Pistons are of the slipper type in aluminum with two narrow rings.

The inlet valves are of the Ricardo masked type having their seatings recessed in the valve pocket, so that a quick effective opening and cut-off is secured, with a comparatively gradual initial and final movement, from and to the seat respectively.

This new engine is not yet standardized, has not, in fact, yet passed the experimental stage; but it is intended eventually for the Triumph standard machines, displacing the 550 c. c. 4 h.p. side valve engine used for some years past. Its bore and stroke are 80.5 x 98 mm. and it is designed to run up to 5000 r.p.m. The peak of its power curve reaches 20 b.h.p., admittedly a remarkably high output for a single cylinder of this size.

The B. S. A. Company also put up a special overhead two-valve engine for the Isle of Man (Tourist Trophy) Races. This, too, has a single cylinder and a peculiar feature of the valve system is the adoption of "knife edge" bearings for the overhead rockers.

## New Make of Laminated Wood Disk Wheel

**A** VEHICLE wheel in which a disk of laminated wood takes the place of the usual spokes has recently been developed. The wheels are made from the same grades of wood as used for airplane propellers and are laminated in such a way that the grain in each lamination runs in a different direction from the grain of the other laminations.

These wheels are claimed to be of about the same weight as spoked wheels but to have four times the lateral strength. Tire inflation does not involve any unusual difficulties with this wheel, the air tube being attached to the outside of the wheel. The air valve pocket has a flat cover front and back, so there is no projecting part to be knocked off and no open pocket to catch dirt. No spare wheel needs to be carried, only a spare rim with tire. The wheel is manufactured by George W. Smith & Co., Inc.

# Machining an Eight-Cylinder Crankcase

A production of 20 engines per hour is maintained in the new engine plant discussed here. Machining the crankcase presents problems in the construction of jigs and fixtures. Many special machines are used to produce this eight-cylinder, V-type aluminum crankcase.

By J. Edward Schipper

**M**ANUFACTURE of the crankcase for an eight-cylinder engine entails some very interesting production problems on account of the V-construction. In order to have the proper angle between the blocks, the landing faces for the cylinder flanges are, of course, at a complementary angle. Some difficult manufacturing problems must be solved, particularly in the way of jig and fixture construction, in order to perform simultaneous drilling and other machining operations.

The new Oldsmobile engine plant, which has been completely tooled and equipped for the manufacture of the small, eight-cylinder engines, is arranged for a production of about 20 engines per hr. The operations on the different machines are all timed for about this pace, and the machine tool equipment is very closely balanced so that practically all of the machines are in operation during the entire 9-hr. working day to maintain a smooth flow of manufacture. The crankcase material is aluminum and of orthodox construction.

The finished crankcase is shown in Fig. 1, receiving its final inspection. This finished view of the case will give an accurate idea of the machining problems required for its manufacture. As will be noted, it is a unit powerplant type of case and has the camshaft centrally located above the crankshaft, as is customary in eight-cylinder, V-practice.

The crankcases are first checked over to determine if there is sufficient metal for all machining cuts. The locating points are checked at the foundry. There are three locating points, two supporting arms and the boss for the oil line, which runs to the front camshaft bearing. These same locating points are used for the first manufacturing operation, which consists of milling the oil pan or bottom face of the crankcase. This work is done on an Ingersoll miller with a rotary table. The machine holds five cases and gives both a rough and finish cut. There are three cutters, two being for the rough cut and one for the finish cut. The cases are secured to the table by clamps which hold the supporting arms of the case and location is fixed by stops at the points described. The machine readily takes care of 20 crankcases per hour, and provides practically continuous cutting, the operator being only required to load and unload the cases on the rotary table. This machine, which is illustrated in Fig. 2 is a special machine made by the Ingersoll company for this particular work.

After the oil pan face has been milled off, the milled face and the dowel pin holes are used for locating practically all of the following operations. The next operation is to drill and ream the oil pan and dowel pin holes. The work is done on the Leland-Gifford two-spindle machine. The work is located from the oil pan face and the two pads

on the right side of the case. There is a V-block for end-wise location.

An Ingersoll miller is used for facing off the timing gear ends of the crankcase and also the generator and distributor pads. These pads are on the top surface of the case and the work necessitates the simultaneous operation of three cutters. The machine is designed to be loaded while in operation so that a minimum amount of time is lost between cuts.

Another Ingersoll machine mills the main bearing surfaces and the motor support arms. This requires three cutters, the operation being shown in Fig. 5. The location for the work is from the oil pan face and the two pads on the right side of the crankcase. Following this operation, the cylinder contact face is rough milled on an Ingersoll milling machine. The location for this work is from the dowel holes and the work is handled by putting the crankcase in, first on one side and then turning over to the other side to take care of both cylinder block contact faces. A similar machine is used for taking the finish cut on these contact faces, the operation being similar to that shown in Fig. 6, which illustrates the rough cut.

A 22-spindle Foote-Burt machine drills all the holes for the main bearing studs, for the main bearing dowel holes, the oil pan holes and the motor support holes. The work is located from the dowel holes and the crankcase is handled in a pedal operated, elevating jig. This is a very good example of special machine drilling work and is illustrated in Fig. 7. Another very good illustration of this type of work is in the following operation, which is also handled on a Foote-Burt machine, as illustrated in Fig. 8. The work consists of drilling the oil pan holes and also the holes for the clutch housing, crankcase cover, rear, gear-case cover, front cam bearing stud, distributor brackets, spark control brackets, generator bracket stud, main oil line, and the oil pressure gage screw hole, giving a total of 77 spindles. It is a four-way machine and supplants equipment which a few years ago would have comprised from five to ten machines. This work is all located from the dowel holes.

For drilling the center cam bearing lock screw hole and the front cam bearing oil hole and spot facing both these holes a 3-spindle Leland-Gifford is utilized. These are all separate operations done one at a time on this machine as illustrated in Fig. 9.

One of the operations which illustrates the special machine required for eight-cylinder V-type crankcases is illustrated in Fig. 10. This is a Foote-Burt, two-way machine, which reams the piston clearances and drills the holes for the cylinder contact studs, the dowels for the cylinders, oil returns and main bearing oil leads. The machine also reams the cam bearing lock screw holes and the

 15—Tapping main bearing stud holes and oil pan screw holes with 31 spindle Foote-Burt machine  
 16—American radial utilized for retapping oil pan and other screw holes  
 17—Rockford horizontal drill for rough boring cam and crankshaft bearings  
 18—Two-way Foote-Burt machine for drilling valve lifter guide holes

19—Holland radial and tumble jig used with indexing fixture for drilling valve lifter guide stud and other holes. 20—Reaming distributor bracket hole on Foote-Burt machine. This machine also drills and reams oil pump shaft hole and other openings in the case. 21—Ingersoll machine for milling clutch housing and rear crankcase cover. The work is located in this operation from the crankshaft bearing by means of bar which passes straight through. 22—Facing front camshaft bearing on Cincinnati drill

breather tube and oil gage holes. It handles the work for all eight cylinders at a time, having 39 spindles and being a specially designed machine throughout, particularly for this V engine. The machine has a capacity of from 20 to 30 crankcases per hr., which readily allows it to take care of capacity production by the rest of the machines in the shop.

A special, three-way, Foote-Burt taper taps the clutch housing holes and also the holes for the rear crankcase cover, control brackets, distributor brackets, generator bracket pad, main oil line, gear cover stud, and the front cam bearing stud. This necessitates 48 spindles for the work and the holes are all tapped simultaneously. It will be noted from the illustration that in practically all of these operations the crankcase slides on the jig and the locating dowels are elevated when the case is in place. The nature of the machine equipment for a V-type of engine is again brought out by the two-way Foote-Burt taper shown in Fig. 12. This machine taps the cylinder block stud holes, the rear cam bearing lock screw holes, the main bearing oil line holes and reams the breather holes and the holes for the oil gage. The location is by the dowels as for the other similar operations and the clamping arrangements for the work are also similar.

The profiling operation for milling the valve lifter guide seat is done on an Automatic Machine Co. profiler with three cutters. This operation, which is shown in Fig. 13, is handled at the rate of 20 per hr. readily, so that this machine holds its position in the production line and balances with the rest of the shop equipment. A Milwaukee miller, shown in Fig. 14, mills the valve inspection cover face. This work is located from the cylinder dowel holes and the jig is so arranged that the work can be turned over for the similar operation on the other side of the case. A Foote-Burt taper taps the main bearing stud holes and the oil pan screw holes. This is a 31 spindle operation and is shown in Fig. 15. The same dowel location is used for this work.

In order to be sure of the size and quality of the threads in the oil pan screw holes, an American radial is utilized for re-tapping all of these holes and also the main bearing stud holes. This machine drives 8 studs and the bearing and cap is assembled on this same operation. The nuts are put on the studs and the machining shims put in place in the bearing. An Errington tap chuck with a friction release is used for putting on the nuts with uniform tightness.

After this operation, the work is passed along to the

Rockford horizontal drill shown in Fig. 17. This rough bores the cam and crankshaft bearings on Kelly reamer bars. To expedite the work, a rotary indexing table is utilized so that one may be loaded while the other is being cut. The table is then swung around, indexing properly for the operation to go ahead on the next case while the first case is being unloaded and another slipped in place.

Another Rockford horizontal drill exactly the same as for the previous operation is used for facing the crankshaft bearing. The Kelly bar has four cutter slots, allowing two cutters to work forward at a time and then two back at a time. Another machine of the same description is used for making the finish cut.

After the bearings have been cut by this method, the case is forwarded to a Foote-Burt, two-way machine for drilling the valve lifter guide holes, as illustrated in Fig. 18. These are all drilled simultaneously and the crankcase is then passed to a Holland radial drill, which drills the valve lifter guide stud holes, the main oil line holes and spot faces the control bracket bosses and the oil gage bosses. This work is handled in a tumble jig with an indexing fixture, illustrated in Fig. 19.

The case is then reamed on a Foote-Burt reamer which

takes care of the distributor bracket hole and also drills and reams the oil pump shaft hole and distributor drive shaft hole. This is a single spindle machine. This machine also finishes the distributor boss, using a combination facing tool and reamer.

The crankcase is stood on end for the next operation, which takes place in an Ingersoll milling machine. This mills the clutch housing and the rear crankcase cover. The work is located from the crankshaft bearing holes by means of a bar which passes straight through. There are five cutters on this machine taking care of this work. The operation is shown in Fig. 21. The front camshaft bearing is faced on a Cincinnati drill, the work being located from the dowel holes. This operation is shown in Fig. 22. The crankcase is then passed to a Holland radial drill which takes care of the rear crankcase cover dowel holes, the oil return pipe holes, two stud holes in the main oil line and drills on top the oil line lock screw hole in the front end of the case. The finishing operations on the case consists of drilling the bearing studs on a Hammond radial and tapping the valve lifter guide stud holes on a two-way, eight spindle, self-reversing Leland-Gifford automatic tapping machine.

## Some Recent Automotive Developments

### A French Solid Tire

**A** NON-SYMMETRICAL dual solid rubber tire has been put on the French market by Bergougnan specially for use on the rear wheels of 3 to 7-ton trucks. It is claimed that this new construction combines all the advantages of the round with the flat tread tire without any of their respective disadvantages, and is an improvement on the big single solids commonly employed by American makers.

The recognized advantages of the flat tread tire are

The Bergougnan non-symmetrical dual solid rubber tire for use on heavy trucks. It is employed on the Renault 7-ton trucks.

that it conforms to the profile of the road, the load is spread over a bigger surface and it is less inclined to heat. On the other hand, the flexions of the tire under load break down the walls and have a tendency to loosen the soft rubber from the hard rubber base by which it is secured to the steel rim. This tendency is considerably reduced with the round tread tire, for the pressure is transmitted through the axis of the tire; as a disadvantage, the area in contact with the road being reduced there is a greater tendency to overheat.

On the new Bergougnan the two rubber bands are brought closer together than usual, as shown in the illustration, giving the theoretical advantages of the flat with the practical advantages of the round profile.

### New 10-Ton Caterpillar Tractor

**A** NEW 10-ton tractor model specially suited to conditions on the Pacific Coast is announced by the Holt Mfg. Co. It has a rating of 60 hp. on the belt and 38 hp. on the drawbar. Among the new features are pressure oil feed to the crankshaft bearings and better protection of working parts from dust and dirt. The valve push rods are enclosed, the breather and oil filler is of a new

type claimed to be dust and dirt proof, and the cylinder heads are completely covered. A new type of air cleaner is included among the items of standard equipment. The transmission has large bearings and cut steel gears.

This new Western model is designed particularly for orchard and road work, logging and general farm work. Full spring mounting is provided. The split truck construction makes the tractor flexible and adapts it to work on extremely rough ground. The driver sits on a cushioned swivel seat and controls the brakes used for steering with his feet. The steering column carries the spark and throttle controls and the two-armed clutch control that releases the drive to one or the other of the tracks. Hand levers control the main clutch and gear shift. A geared hand starter is operated from the driver's deck. The fuel tank is filled from the deck and the flow of oil to the tracks is controlled from there also. Access to the engine can be gained by removing the engine hood and the interior of the engine can be reached by taking off large hand-hole plates.

### Aluminum Piston with Cast Iron Skirt

Chase composite piston

**T** P. CHASE, formerly chief engineer of the King Motor Car Co., has invented a piston with the head and wrist pin bosses cast integrally of aluminum, while the skirt or remaining portion of the piston is formed of cast iron. In this piston the aluminum is cast on the iron portion. The piston is illustrated in the accompanying part sectional view.

# Insurance Is a Sales Resistant

Present methods of handling automobile insurance are not satisfactory. Mounting insurance rates are increasing resistance to car sales. It costs more than \$150 a year in one town of 175,000 to insure a well-known car for fire, theft, liability, and collision. That is enough to make a man think twice before buying a car. The problem must be considered.

**E**VERY factor which acts as a sales resistant is being closely scrutinized by the manufacturer. The mounting costs of automobile insurance are of serious concern, since the item of insurance has now grown to such proportions as to be an important financial factor in car ownership. When an ordinary owner is compelled to pay several hundred dollars a year insurance, in addition to the regular garage and upkeep charges on his car, he is apt to count his resources more carefully before buying the next car. Especially is this true since insurance rates give no indication of having reached a maximum.

One of two things is likely to happen in the case of any individual in the class of what may be called marginal car buyers: those who have just about enough income on which to operate a car but not much more. Such a man is likely to buy the car and take a chance without insurance or simply do without the car.

It will be readily granted, probably, that insurance rates have become a definite sales resistant; that they have increased enormously during recent years. The question of responsibility and possible remedies then arises. It is not possible to decide these questions fully at the present time, especially within the scope of a brief article. The manufacturer should be interested, however, in a brief outline of the situation as it now stands, the contentions, and opinions of some of those concerned on both sides of the case, and an indication of what improvement may be expected from future developments.

There are four kinds of automobile insurance to be considered, each of which presents a somewhat distinct problem. These are:

1. Fire
2. Theft
3. Collision
4. Liability

## Fire and Theft

Fire and theft insurance are usually written in one policy and present similar problems to a large extent. The theft question was discussed at length at a recent meeting of the Metropolitan Section of the S. A. E. At that meeting automobile men, police officials and insurance men voiced their various opinions. The expressions of this meeting, together with interviews with a number of persons intimately connected with this work, gives a clear general idea of the present situation.

The N. A. C. C., representing the views of the manufacturers, feels that the reason for high insurance rates is "the loose methods of accepting risks" used by the insurance companies. It has been the habit of the insurance companies to write fire and theft insurance up to the full value of the car. Since a car continually depreciates, of course, this practice makes it actually profitable for a man to have his car stolen.

Such a condition is a direct encouragement to the dishonest man and is an incentive to carelessness on the part of the average owner. The objections to present methods of writing such insurance can probably be best stated by quoting from the statement recently issued by the N. A. C. C. This statement says in part:

"The moral hazard receives no consideration. A burglar just out of jail gets the same rate as a respectable citizen.

"The amounts allowed on cars and trucks almost encourage their being burned up or destroyed to be reported as stolen.

"We hear many times of legislation to force everyone to take a bond on their car on the ground that it would prevent accidents. Such action would make accidents more frequent because it would shift the responsibility of the driver.

"It would be of more help in preventing accidents if no owner was permitted to carry liability insurance and no car was equipped with a horn.

"A sedan insured new last year for fire, transportation and theft to the amount of \$2,600 at a cost of \$33.80 has just been renewed at a cost of \$55.00 and is now covered for \$2,500. The policyholder in this case is displeased at the amount of the premium and surprised at the amount of the coverage, as he would gladly take \$2,000 for the car.

"At the same time we read, within the last few days, of several automobiles being found in Lake Erie, near Buffalo, where they had been intentionally dumped, another in New York Bay and a half dozen in an old quarry in Illinois.

"These facts undoubtedly throw a great light on the high cost of automobile insurance, and it is evident that the methods of writing ordinary fire insurance on buildings and furniture without actual knowledge of the value of the property insured, will not do at all for automobiles."

## Companies Changing Attitude

The attitude is that the insurance companies care chiefly about writing as high amounts of insurance as possible because the higher the amount the greater is the broker's commission; that the increase in rates is a matter of little moment.

An examination of the situation indicates, however, that there is something to be said on the other side of the case. As insurance rates rise, a greater sales resistance is created for the insurance companies as well as for the automobile manufacturers. The insurance brokers have a problem of salesmanship on their part. Some of them, at least, realize that lower rates would probably mean the writing of a greater amount of insurance. In any case, the insurance companies claim that they are constantly striving for minimum rates and that they are directing strenuous efforts in that direction.

A new type of policy is being written by the so-called conference companies which is a step in the direction of removing the incentive to dishonesty previously mentioned.

This is what may be called a non-value policy. It insures a car without naming a definite value. Then when the loss occurs, the value is determined by the used car value of the car. If a 1921 Buick were insured to-day, for instance, and were stolen in 1922, the owner would receive from the insurance company the value of a 1921 Buick at that time.

This policy meets many of the objections raised, and while not the last word, is a definite step in advance. It is still possible, however, for the owner to get definite value fire and theft insurance from certain companies. The chief difficulty with the non-value type of policy is well stated by C. S. Disbrow, president of the American Automobile Insurance Co., who says in a recent number of *The Weekly Underwriter*:

"Some underwriters maintain that any amount of insurance may be granted if a non-valued form of policy is used. This is not so. The psychological effect of the large insurance policy and the much smaller sales value of the car is still there. Few assured know the meaning of the non-valued policy and the broker is apt to gloss it over. . . . In some states the law makes all policies valued anyhow. . . .

"If the companies wish to eliminate crooked losses it is easily within their power to do so, either by lowering the amounts of insurance or by issuing a daily or monthly depreciating policy, so that the amount of insurance will at no time exceed the trading in value of the car."

The manufacturer has several sources of direct, but comparatively unimportant, contact with the matter of fire and theft rates. These are in connection with identification systems, theft locks, and mechanical construction and equipment as regards fire hazards.

A number of suggestions as regards identification systems have been made and work along this line is already being carried on. It would probably be to the advantage of the manufacturer to equip his cars with a recognized theft prevention device. In New York City at the present time there is a definite insurance rate penalty of \$25 on the car not so equipped, while the car that is equipped saves that penalty and 15 per cent besides. The manufacturer can always equip a car with such a device, of course, cheaper than the owner can buy it retail after he has purchased the car.

The Underwriters' Laboratories are carrying on extensive tests for the purpose of classifying automobiles as to protection against fire and collision hazards and their equipment of theft retardants. The schedule recognizes seven principal groups of items affecting the fire hazard and to each group is assigned a certain proportion of the total points to be used in rating. While these tests are very comprehensive and the results are likely to be excellent, their importance is minimized by the fact that the factors which they consider are of slight moment when compared to the larger factors just discussed here. The chief difficulties lie in methods of writing insurance rather than in mechanical features of car construction.

### Collision Insurance

Methods of writing collision insurance have been subject to many of the criticisms directed against fire and theft methods. It has been objected that the driver, being fully covered for all damages to his car, was likely to be more careless in driving than if he had some personal responsibility in the matter.

A number of the larger companies have recently eliminated full coverage collision insurance. The policies written by these companies now make the owner responsible for the first \$50 or \$100 of each collision loss. Such a policy tends to make the owner more careful and at the same time gives him insurance in case of a serious accident. Thus it operates to the benefit of all concerned, as

well as reducing expenses for the insurance companies by eliminating the handling of small claims which cost more in overhead than in actually loss payment.

### Liability Insurance

Liability insurance constitutes the most important phase of automobile insurance both from a financial and a human standpoint. The cost of fire and theft insurance is not nearly so large actually as liability insurance, while the rise in liability rates means more than money—it records an increase in human suffering and the loss of human life. It is a matter of record that the number of automobile accidents have increased in this country during recent years. But it is not this increase alone that has caused liability insurance rates to advance. The claim cost to the insurance companies has increased greatly. That is, the cost of court actions, payment of awards, etc., have increased per case; an increase not affected by the actual increase in accidents. The figures for one of the largest companies, for instance, run something like this:

The cost per liability case in 1918 was 24% greater than in 1917.

The cost per liability case in 1919 was 45% greater than in 1917.

The cost per liability case in 1920 was 60% greater than in 1917.

This increased cost has been brought about largely by the increased amounts which juries have been awarding to injured persons in liability suits. As the cost of everything has risen during recent years and as people have lived on a more expensive scale, so have the liability awards kept pace. This fact, together with the tremendous increase in the number of accidents, has sent liability rates far up, until they are now a very large factor in the minds of many prospective automobile owners.

There is nothing being done as regards liability policies that is analogous to the elimination of the full coverage collision policy. In other words, it is still possible for the owner to insure himself for a large amount and then run down a man or woman without losing a cent. It would certainly seem logical to provide some form of policy which would place a certain amount of liability on the owner of the car. Such financial liability might go a long ways toward reducing the number of accidents.

Among the chief faults attributed to present insurance methods is that of failure to properly consider the moral hazard when writing insurance and of failure to properly investigate claims after accidents have occurred. Both of these things could be discussed at great length without any decision being reached, as conversation with several persons interested in one side or the other indicates that there is a very great deal to be said on both sides.

### The Mutual Company Idea

The mutual insurance company idea is being seriously discussed as a means of relief from high insurance rates. To quote again from the N. A. C. C. statement on this subject:

"It is very well to say that one who uses the mutual assumes a liability, but this is losing force from experience to the contrary; dividend of from 25 per cent to 50 per cent, compared with standard rates, have for long periods been received on premiums by their policyholder.

"According to figures given out by 131 insurance companies the fire and theft premiums received by them in 1920 amounted to \$74,472,250. The losses paid amounted to \$42,985,748. It would be interesting to know the proportion of these losses that went to reimburse such costs as noted above (i. e. to careless or dishonest owners).

"Surface indications certainly point to urgent necessity of scrutinizing this moral hazard.

"The makers are convinced that insurance would have offered a much greater sales resistance than it has were it not for the relief offered through lower rates from mutual companies which are operating in all sections of the country."

The objections to the mutual company may be summed up as follows:

1. The ever-present, though perhaps remote, possibility of assessment of the members
2. The lack of facilities for proper service. The big insurance companies with their branches are equipped to render instant and competent service in any part of the country, while the mutual company is likely to have to depend upon a local agent of some kind.
3. In fighting court cases, in paying claims promptly because of the necessity of preserving good will for future business, in permanency and stability, the regular large insurance companies are equipped to render many services not possible in the case of the mutual company.

One insurance man put it something like this: "Yes, you can get lower rates at the mutual companies. You can buy fish at a cheaper price if you go down to the dock and carry it home; you can get the fish for nothing if you go out and catch it. The regular insurance companies render a service for their higher rates that is far more valuable than the difference in the rates."

It has been suggested that a law compelling every car

owner to carry insurance might be of advantage. It is argued that such compulsory insurance would protect the pedestrian by making every driver financially responsible and would benefit the driver by setting definite money judgments for specific injuries.

The effect on rates of such a law is problematical. Some insurance men, for example, believe that it would tend to reduce rates because of the greatly increased number of persons who would be paying insurance premiums. Moreover, the stated amount for injuries would tend to reduce the amounts necessary for the insurance companies to pay out to injured persons, with a corresponding decrease in cost per case.

On the other hand, the fixed judgment limits and the freedom from financial liability on the part of the driver might increase careless driving and the taking of risks. It would place the driver at the mercy of the insurance companies to some extent, as their rates would be governed then only according to competitive rates of other companies and not by the sales resistance factor which now operates. This would not be true, of course, if the rates were regulated by the law.

It is not the purpose of this article to decide the merits of the case; the two sides have merely been presented for the consideration of the manufacturer. The entire problem of insurance is important at the present time and calls for serious and thoughtful consideration by the automobile manufacturer.

## A Steel Disk Wheel

A STEEL disk wheel the disks of which are spoked on their circumference is shown in the accompanying cut. Lightness and the possibility of quick tire changes are claimed as the advantages of the design. The disks are solid to within  $3\frac{1}{2}$  in. of the rim, where they branch into spokes. They are of convex shape and come together on the circle where the disks and spokes join, the eight spokes of the outer disk abutting an equal number of lugs on the inner side of the rim and the spokes on the inner disk abutting lugs on outer side of the rim. This trussed construction gives great strength to resist lateral stresses, it is claimed. The disks are further reinforced by beading. Disks and rim are held together solely by the pressure of the hub nut, the radial component of this pressure against the rim lugs amounting to 15 per cent of the total pressure. A locking device is incorporated in the nut.

It is claimed that the wheel will always run true, even though the rim might have been out of true before assembly. The disks are secured to the wheel hub by means of six or more studs. As compared with the full disk wheel, the advantage is claimed that there is no interference with access to the tire valve. As regards weight, it is

stated that the 30-in. wheel is 10 lb. lighter and the 32-in. wheel 15 lb. lighter than the standard wood wheel.

When a tire and rim change is to be made, the hub nut is loosened (not removed), which allows the plates to contract. The finger is then placed on one side of any spoke in the outer disk and the disk is rotated so as to clear the lug, whereupon the rim and tire may be removed. The disks are made of molybdenum steel, the hubs and hub nuts of malleable iron or forged steel, and the brake drums of pressed mild steel. It is the intention of the manufacturers, the Rey Wheel Co., to first put out a Ford wheel of this design, to be followed by 30, 32 and 34 in. sizes.

## New Stewart Speed Truck

A NEW 1-ton speed truck is announced by the Stewart Motor Corp. The machine is claimed to cover from 14 to 16 miles on one gallon of gasoline, to be capable of a maximum speed of 40 m.p.h., and to be able to negotiate grades of 22 per cent with capacity loads.

The engine is a Buda four cylinder  $3\frac{3}{8}$  by 5  $\frac{1}{8}$  in. Ignition is by Eisemann magneto, and the carburetor is a Zenith. Fuel is fed by gravity from a 16 gal. tank under the seat. Engine lubrication is by the full pressure system and chassis lubrication by the Alemite system. The radiator is of the cast iron armored type with vertical tubes and has a capacity of 5 gal. The clutch is of the multiple dry disk type making use of molded asbestos disks. Annular ball bearings are used on the transmission shafts. The rear axle is a Clark internal gear drive type with a 6.75 to 1 reduction ratio. Other ratios are as follows: Intermediate, 11.48 to 1; low, 27 to 1, reverse, 30.38 to 1. Frame side rails are of channel section of the following dimensions:  $4\frac{1}{2}$  x  $2\frac{1}{4}$  x  $\frac{3}{16}$  in.

The truck is equipped with 35 x 5 in. cord tires all around. The regular equipment consists of electric headlights, electric tail lamp, tool box, 111 amp.-hr. Willard storage battery, tools, jack, horn, etc. The price of the chassis f.o.b. Buffalo is \$1,875.

Rey steel disk wheel

## Aluminum Pistons

Editor, AUTOMOTIVE INDUSTRIES:

We have read with much interest Dr. Rosenhain's article on "Problems and Possibilities of the Aluminum Piston," which appeared in your publication for June 16, 1921. On the whole this article brings out many interesting and valuable points concerning the aluminum piston. A few statements in the article lead one to believe, however, that Dr. Rosenhain is not familiar with all of the latest developments made in aluminum pistons. In the paragraph headed, "Advantages and Disadvantages of Aluminum Pistons," he mentions the higher co-efficient of expansion of aluminum over that of cast iron. This, of course, is quite true. Recent experiments, however, have definitely shown that the maximum temperature drop is across the rings, which would seem to indicate that most of the heat leaves the piston through the rings, leaving the skirt comparatively cool. Dr. Rosenhain makes a statement later on in his paper exactly opposite of this, inasmuch as he states that most of the heat leaves the piston through the skirt. The temperature of the skirt is not high enough to account for all of the clearance it was formerly necessary to give aluminum pistons, even though the co-efficient of expansion of aluminum is about twice that of cast iron. The only conclusion that can be reached is that the skirt expansion can be divided into two parts:

- (1) The thermal expansion due to the actual temperature of the skirt.
- (2) A mechanical expansion due to the thermal expansion of the head.

The head being so much hotter than the skirt will naturally expand more and to a certain extent will pull the skirt of the piston with it. To make this skirt expansion harmless a new design having a slot separating the head from the skirt immediately below the last ring on the thrust faces has been made. The head can, therefore, only distort the piston skirt along the axis of the wrist pin. This expansion is made harmless either by relieving the piston on the side or by means of a vertical slot in the low thrust side of the piston. The expansion of the piston skirt along the axis of the wrist pin actually sets up forces tending to contract the piston across the thrust faces which still further reduces the clearance necessary. Pistons of these designs as well as the temperature distribution obtained by actual measurements were discussed in a paper which the authors read at the Buffalo Section of the S. A. E. and which appeared in the S. A. E. Journal, issue for May, 1921.

It seems as though Dr. Rosenhain were laying too much stress on the reduction of strength of aluminum piston alloys at high temperatures. Piston failures due to the metal actually failing in pistons has been very rare, particularly in automobile engines.

Under the heading of "Piston Pin Bushings and Piston Rings," the statement is made that when a floating pin is used it is necessary to cast in, or screw in a cast iron bushing. It has been the experience with aluminum that it affords an excellent bearing surface for a hard-

ened steel wrist pin and the practice of inserting bushings of any description for floating wrist pins is not general, in fact, it has been resorted to only on very few occasions for the simple reason that the performance obtained by simply floating the pins in the aluminum has given such good results. It is, of course, necessary to make the pin a rather tight fit when the piston is cold.

Piston rings have, in the past, given trouble both in aluminum and cast iron pistons. Experience seems to point toward the use of the narrower rings than have formerly been in use. Under no circumstances should an eccentric ring be used in an aluminum piston.

FERDINAND JEHL,

Engineers of Aluminum Manufactures, Inc.

## Standardization and Individuality

Editor, AUTOMOTIVE INDUSTRIES:

Mr. T. V. Buckwalter's letter in your June 9 issue demands attention mainly for the fact that it comes from Mr. T. V. Buckwalter. It is, however, an example of the somewhat loose talk and discussion that is given to this question of standardization. It is a curious thing that the pendulum in this discussion seems either to swing to the extreme right in favor of complete standardization or to the extreme left in favor of none at all. Surely there is some middle, logical, scientific ground on which we can reason out this subject very fully.

Mr. Buckwalter believes that I think that the automotive industry exists primarily to furnish employment to certain classes of workers. I am at a loss to understand why he should so think, but at the same time even this is a pretty good excuse why the question of standardization should be approached with great care. Would anyone want to see the automobile engineer eliminated? Mr. Buckwalter states that it is undoubtedly true that standardization may result in a certain loss of individuality to the engineer.

This is something very greatly to be deplored. The engineer is the brains behind the design and in many cases behind the construction and production of the vehicle. He is the available human mechanism that brings forth the improvements on which we must run. One has only to contrast the automobile of to-day with that of three years ago, six years ago, nine years ago, twelve years ago, and so on in cycles of three years, to realize the wonderful steps that the automobile engineer has taken. I believe that this has been brought about by the fact that the automobile engineer has a freer scope in individuality of design than the engineer of any other industry. This is typified by the fact that the N. A. C. C. has practically pooled all patents, thereby giving engineers a free range.

At the root of industry you will find a desire to work by certain men. It has been stated that a particular industry is nothing more nor less than the shadow of one man, and behind the incentives that lead this man to create the industry you would find a desire for work and opportunity for himself. Only under conditions

where a tremendous service would be done to the people would the taking away of incentive from a body of men be desirable. One has only to read Mr. Harry Tipper's articles to appreciate the effect of incentive in the human field.

Mr. Buckwalter is very imperative in his statement that "industry must face this fact, that the great American public has let it be known in a most emphatic manner that less expensive automotive transportation is demanded." If this were so, one could readily see a line of people waiting at the doors of the Ford company or the Chevrolet company, and the salesrooms of all other automobile companies absolutely deserted. Mr. Buckwalter has evidently not yet learned that the great American public is composed of a series of strata depending largely upon their incomes. Those with the lowest incomes are naturally content with the cheapest car. Those with greater incomes want better and better cars—the element of the cost of transportation not being the only thing by a long way that enters into the question. I myself have sold a limousine because the color of the upholstery matched the color of a lady's dress.

Naturally, some of this talk does not pertain to the realms of motor trucks, but it is quite conceivable there should be a standard front axle for a one-ton truck and a standard front axle for a two-ton truck, and so on up to the five-ton truck capacity. After reading Mr. Buckwalter's article I am tempted to ask him if he can furnish any good reason why there should not be a standard truck of each capacity. In fact, going back to the war days, why should we not have a standard  $\frac{3}{4}$ -1-ton truck like the Class AA, a standard  $1\frac{1}{2}$ -2-ton truck like the Class A, and a standard 3-5-ton truck like the Class B? Ask the various manufacturers if they would like this, and ask the customers if they would like this, and I believe the answer would be emphatically no. There must be free competition in order to get reduced costs and, what is just as important, improved results.

I stated in my original article this hub standardization has been called for largely because of a failure to standardize the size of taper roller bearings, and in this matter I cannot hold Mr. Buckwalter or his company altogether innocent. At the present moment, although there is an S. A. E. standard for taper roller bearings, it is very rarely used, and, to the best of my recent knowledge, the Timken company has not recognized this standard. There are certain fundamental things which should be standardized, and the size of taper roller bearings is one of them. Not only does the standardization of taper roller bearings affect the front hubs, but it affects the rear hubs, transmissions and other places where taper roller bearings are used. This would be a real far-reaching standardization and of international character.

At the present moment the ball and roller bearing division is considering new standardization work and has held this up due to the fact that Timken are changing their sizes and want a further revision. In other words, the printed, approved S. A. E. taper roller bearing standards are held farcical by one of the leading members of the specific industry.

I believe it was in 1916, at a standards meeting in Cleveland, that I pointed out the desirability for standardizing the boundaries of contact in fundamentals and not details. I still believe in this. I believe, for example, in the standardizing of certain widths and gages of steel for springs; I am a believer in the standardization of rims for all tires, so that one can buy a tire anywhere along the road. Tires do wear out, it is a recognized fact, and therefore there must be a standardization of the boundary of contact between the tire and the vehicle. I am a tremendous believer in standardization in one's

own shop, making the smallest number of models or products that will fill the demand, and standardizing these and their component parts to the best possible combination. I still feel that the introduction of a standard has quite often meant merely the addition of another article to be manufactured.

I had an experience some years ago when I sought to standardize bushings for a line of passenger cars and trucks, five models in all. I confess I found it an impossibility, as the bushing is so often used as the flexible link in a chain of mechanism, and yet, at first glance, the bushing would seem to be something which should be standardized. Similarly with a great many other parts. It is so easy to find reasons why one should not adhere to standards, as they often give way before the elements of expediency.

I apologize for taking up so much of your space on this matter, but the question of retaining our individuality and of keeping in the line of progress, not merely from a cost standpoint, but from the final result standpoint, is so strong within me that I feel I have to answer this. I just received a letter from the headmaster of the largest technical school in the city of Glasgow—Dr. John G. Kerr—in which, in connection with another matter dealing with the standardization of examinations that are given to young men before they start out in the universities, he states: "I may perhaps be wild in my belief about the importance of individuality, but that belief grows more and more with the years." This statement is made by a man who has had the training of men in his hands for some fifty years. I think you will find the desire to escape from monotony one of the strongest incentives of the human race.

JOHN YOUNGER,  
Vice-President, Standard Parts Co.

## Horsepower Correction Factors

Editor, AUTOMOTIVE INDUSTRIES:

In your June 30 issue appeared a Horsepower Correction Alignment Chart, which is based on the assumption that power is proportional to air density. The Bureau of Standards tests and many others have shown us that power is not proportional to density for temperature changes. Is the assumption used correct? The power should be proportional to air density if the volume were constant, which would be the case if the engine were a straight displacement proposition. This is not the case, however, with the air passing through poppet valves. These have the effect of orifices and the air flow should be investigated on air orifice flow bases. An examination of the orifice equations for air flow will show that the volume of air changes with temperature, which eliminates the density assumption as far as temperature changes go. Further examination of the orifice equations will show us that the horsepower

should vary as  $\frac{1}{\sqrt{T}}$  absolute. Therefore our correction formula should be

B.Hp. (corr.) = B.Hp. (obser.)  $\times (P_s \div P_o) \sqrt{T_o \div T_s}$ ,  
where  $P_s$  and  $P_o$  are respectively standard and observed barometric pressure and  $T_s$  and  $T_o$  are standard and observed absolute temperatures.

The writer has checked this formula against "air temperature vs. power" tests from different sources, including part load tests, and found that the horsepower change was very well expressed by this new equation, whereas the density assumption showed a change nearly twice as great as actually observed. The Bureau of Standards correction gives practically the same factors as the new equation.

Why, then, should we continue to use a correction for

temperature that is 100 per cent in error? For example, to correct power at 29.92 in Hg. for air of 90 deg. Fahr. we get from the chart a correction of 5.8 per cent., while the Bureau of Standards correction factor shows us that actually the engine would only pull 3.1 per cent more power at 60 deg. Fahr. than at 90 deg. Fahr. With our present day air stoves, raising the air temperature to 150 deg. Fahr. and over, the error involved in these corrections certainly deserves consideration. At least let us question the density assumption until it is shown to be correct. I believe the orifice flow basis to be the correct one to work on and the new equation is the result of work on this basis.

HAROLD S. WHITE.

## Reasons for 56 in. Gage and Contracting Brakes

Editor, AUTOMOTIVE INDUSTRIES:

The remarks by Mr. W. J. P. Moore, published in last week's Forum, in which mention is made of some of the statements made in my letter published in your issue of June 16, in connection with passenger car brakes and passenger car seating capacity are well worth considerable thought.

In regard to paragraph 7 I am under the impression that the standard tread of automobiles is taken from railroad practice in regard to the standard gage of railroads. In the majority of countries this is 56½ in., though there are a number of other gages in use. I do not believe that there was ever any very definite figure in regard to the standard carriage tread, though it has been for years recognized that in the neighborhood of 56 in. was the standard for the Northern States, and, I believe, 60 in. for the Southern States. The writer made the tread during the last fifteen years 56 in., until the time that we used the cross section of tire of 5½ in. instead of the 5 in. that we formerly used. Then in order to provide the same clearance between the rear wheels and the wheel housing and in order to obtain the same lock on the front steering wheels when tires of 5½-in. cross section were used, the tread of 56½ in. was adopted and the slight increase has been appreciated. I believe that there are many reasons why automobile manufacturers in this country should adhere to approximately this tread as standard—the trolley rails are also 56 in. gage and there are many cases where it is desirable to run automobiles along the trolley rails, although this is not good practice where the rails are worn because it may result in badly cut tires. Although there are a great many miles now of improved highway, the vast majority of roads in this country are clay, mud and dirt and these roads have very distinct ruts that make it almost impossible to travel on unless the car has approximately 56-in. tread. Due to the means of repairing roads in this country, it is rarely ever possible to take a trip even along the main highway between such cities as Buffalo and New York without having to make detours which, in most cases, take one along dirt or clay roads, which very soon become deeply rutted.

If the buying public would consent to the elimination of seats to carry three people in automobiles, there is nothing wrong with making approximately 56 in. the standard tread, and there is absolutely no objection to a standard tread of this kind where good concrete, brick or macadam roads are prevalent, as on such roads a car rarely if ever follows in the track of the preceding car. Almost all drivers keep close to the middle of the road except when passing another vehicle when they go over to the right-hand side, so that almost every part of such a road is traveled on and there is certainly no need for cars of varying treads on such roads.

In regard to paragraph 21, in cases where good roads prevail it is an advantage, perhaps, to have a narrow tread on very small cars. This is the regular practice in France and England. In the case of large cars it would appear to the writer to be impractical to have a tread in excess of 60 in. The present design of automobile has had such an enormous start that it will be impractical to-day to make cars of 65 or 70-in. tread, as there are thousands of exceedingly expensive garages that have been built with the width between the doors that only permits of a clearance of 6 in. on each side with the present type of car with approximately 56-in. tread, and it would be impossible to drive into such garages with a tread much in excess of this. Unfortunately many of the latest improved highways are almost too narrow for cars of approximately 56-in. tread and would certainly be inadequate for cars of from 65 to 70-in. tread.

The obstacles in the way of increasing the tread appear to be exceedingly great, whereas the matter of width of seats is largely one of public opinion and is a matter that should be changed without imposing any great sales resistance or any hardship to anyone. Either closed or open bodies have a much better balanced appearance when they are about 10 in. narrower than the regular three-passenger rear seat body. The problems of body construction are much easier to meet in the narrower body—the side window glasses can be made to entirely disappear when down, in a narrow body, the riding of a car can be made much better and the adoption of such a design should result in an advantage all around.

In regard to paragraph 31, unfortunately internal expanding brake shoes rarely give the same efficiency as external contracting brake shoes and the most effective brakes on American cars where both brakes are on the rear wheel, are almost always the external contracting brakes. Many American manufacturers have tried experimentally two internal brake shoes side by side on the rear wheels and found that neither foot nor hand brakes were powerful enough to hold the car. This is especially dangerous when a little oil gets on the brake surfaces, which practically never happens in the case of the external contracting brake. The external contracting brake, when in the form of a band brake, gives very much greater braking surface, and this type of brake can be made to be free from the drum when not in use. The internal expanding brake shoes rarely come in contact for the whole of their surface, in many cases they bear only on the ends of the shoes, resulting in very rapid wear to the brake lining and necessitating very frequent adjustment. The majority of American car manufacturers use the external brake as the service brake because of its being much more powerful and having a great deal more life than the internal brakes.

In the case of four-wheel brakes it is probably essential that external rear brakes will still be required in order that the car may be equipped with two absolutely independent brake systems, so if the foot-brake connection should become severed the driver will always have the hand brake to fall back on with its absolutely independent set of brake shoes, levers, rods, etc.

DAVID FERGUSON, Chief Engineer,  
The Pierce-Arrow Motor Car Company.

## Interchangeable Automobile Parts

**A**UTO Gear Information Service, published by Auto Gear Information Service, is a booklet containing 300 cases of interchangeable gears and axles, including cars from 1912 to 1920, giving the gear ratio on various cars that have identical gears.

# Human Difficulties Predominant in Building Trades Wastes

The recently issued report of the American Engineering Council concerning waste in the building industry indicates that many difficulties grow out of unsatisfactory human relations. Mr. Tipper here analyzes this report and illustrates the significance of the most important points.

By Harry Tipper

**A** FEW days ago the newspapers were quoting quite extensively from the Report of the American Engineering Council upon the building industry and the causes for the inefficiency in this industry. The quotations made in the general publications from this report give a fair idea of the conclusions, but do not indicate very thoroughly the most important reasons for the difficulties.

A very large part of this report is devoted to the industrial relations and evidently the difficulties in the industry are to a great extent human ones due to the lack of co-operation and the misunderstanding very prevalent in this field.

The jurisdictional regulations of the union and the restriction of output very properly receive condemnation in the report of the committee and are indicated as great sources of waste and increased cost.

The restrictions of output by the employer through maintenance of price, collusion in bidding and so forth, are mentioned as further difficulties facing this important line of work.

In regard to low output and the general inefficiency of labor, the committee report states:

"One of the greatest fundamental causes for low output is the fact that all members of unions in the same trade are paid the same wage. There is no incentive. As a result of records made by the authors on actual construction work, it was found that in the building trades on every job there are usually a few men who do one-third more work than the average man on this same job. These men also do better work. Is it fair to these good men for them to receive the same wage as the others?"

These articles have mentioned from time to time the general tendency of uniformity of wages to lead into a uniformity of output below the possible average of a proportion of the men, in other words, the tendency for a uniform wage to bring about a minimum output suited to the average of the less efficient. The more efficient worker will not put forward his power without the incentive of a proportional reward or a difference in the reward established between himself and the other members of the same craft.

Particularly where the other incentives of confidence, visible usefulness and individuality of skill are not emphasized and brought out, the plan of the same wage destroys the only incentive remaining. Despite all the developments of organization rules and regulations, the pay is recognized unconsciously as an indication of the value of the skill. The man who is more skillful than his fellows is

aware of his skill and he is not likely to put forth his extra capacity where it brings no reward of a visible character.

The building trades have been notorious for unruly labor conditions and inefficient management. Generally speaking, the unions in this line of work have been more dictatorial in their attitude and more severe in their adherence to privilege than in the manufacturing trades. On the other hand, the employers have been more mandatory in their attitude, less willing to study and determine the reasons for difficulties and less efficient in their ideas of management.

These things are all brought out in the report and they indicate the enormous amount of waste involved in the building industry because of these inefficiencies and these misunderstandings.

The report deals with the difficulty of the seasonal labor as it is at present employed and the cost of maintaining skilled workers on a basis of about half time in order to provide a sufficient number for the peak loads.

This question of continuous employment or fairly regular employment is a very important one for this industry, but the question should not be overlooked in dealing with the future of more stable industries where the temporary surplus or shortage affects the regularity of employment. We have not yet arrived at the industrial condition in this country which was the usual thing in Great Britain before the war. We do not have periods of low employment in some industry or another every year. In the readjustment we are likely to find that conditions will remain more or less spotty and the unemployment will bring real hardship or require increased taxes, unless measures can be taken to regularize the employment as much as possible.

The economic fear of starvation has not operated very actively in this country because of the easier economic conditions. This fear has had its effect in the strongly disciplined unions in Great Britain and in the bitterness existing between the unions and the employers.

Altogether the report is interesting as indicating the very large percentage of waste obtaining in one of the most important industries in the country and showing that a major part of that waste is due to the human conditions and not to the mechanical arrangements.

The report includes the following statement:

"The most encouraging feature in the building industry to-day is the action of a few of the builders and a few groups of building trade workmen in

making intensive studies of the causes and remedies for irregular employment and haphazard conditions of work. Along with this is the growing appreciation on the part of both labor and management that to build more buildings and maintain high wages it is necessary to attain greater and greater productive capacity per man.

They see as proof of these facts that the 1921 depression was caused and extended by too high costs of all products, and that business, either in manufacturing or in building industries, is improving only as the costs of material and the cost of labor are reducing. All are recognizing, in fact, that no progress can be made without paying greater and greater attention to the elimination of waste.

Never in the history of our country was it so important that certain fundamental principles of economics—principles which are not mere theories, but are based positively on facts—should be accepted and established as a working program.

These principles will throw overboard the fallacy that restricting production can make work go further, and will supplant this with the knowledge to get one must give, that to receive the equivalent must be given in money or in time or in effort, and that increased returns can only be attained through increased production."

It will be seen that the hope indicated in this conclusion is a hope for the betterment of human understanding and relations. In fact, the whole question of mechanical improvement, the reduction of costs, the increase in stabilized employment are predicated upon a greater understanding of these fundamental requirements and a greater co-operation between the builders and the unions in working them out.

This report serves to emphasize what these articles have been stating continually—that the wastes in industry are governed most largely by the human conditions and not by the variations in the mechanical equipment and system.

## Spur Gear Erosion

**F.** W. LANCHESTER in an article in *Engineering* of June 17 describes a peculiar form of failure in the spur gears of motor car change gear boxes, which has been observed repeatedly in recent years. In these cases of failure there appears to be a complete breakdown in the region of the pitch line. Usually the gears brought to the repair shop are in an advanced state of erosion; in that case, although the ordinary involute tooth is convex over its whole surface, there is on each tooth a marked depression—a concavity or groove—running along the tooth about the middle part of its face.

When a pair of gears so affected are mounted on correct centers, it is noticed that the depressions are not exactly opposite each other; they are not symmetrical about the pitch line. Generally speaking, the width of the groove covers that portion of the tooth face from a little below the pitch line considerably outwards towards the point of the tooth, and it appears that when the gears are in action the shoulder of one groove eats into and progressively increases the trough of the other.

In the incipient stage of the pitting there is what appears to be an irregular pitting of the gears in the pitch line region, with a certain amount of radial grooving from each pit. Observation of such gears suggested the following explanation to Mr. Lanchester:—

Where gears are under heavy duty the local pressure between the contact lines or areas is so great that no oil film can withstand it for any appreciable length of time. If the oily surfaces sweep rapidly past each other, as in worm gearing for instance, the lubricant has no time to escape. This also applies to spur gears at points remote from the pitch line region, and consequently the tips and roots of the teeth show no signs of failure. On the pitch line itself, where there is only rolling motion, there is no reason to anticipate injury, even though the oil film may break down, for the action is exactly the same as in roller bearings. But adjacent to the line of actual rolling, and far more important, as it is an area rather than a theoretical line, there are regions or bands in which the motion is very slight and where, while there is insufficient relative movement between the surfaces to drag in lubricant in adequate quantities, there is at the same time a measurable degree of sliding. Here there is definite metallic contact, the oil film having broken down, and at the same time slow rubbing motion under heavy pressure. Under these conditions seizure between the contact surfaces must be expected, or

at least seizure between the surfaces must be regarded as imminent, and a tearing away of one surface by the other.

Furthermore it is quite clear that if we follow the conditions during the passage of a line of tooth contact over the pitch line region we have, before the rolling point is reached, a slowing up of the sliding motion that is symmetrical and in the reverse direction to the subsequent motion after the rolling point is past. Since an oil film takes a certain time to squeeze out, it is evident that the actual metallic contact will tend to take place at or near the rolling point or immediately after that point; the seizure or welding together of the surfaces follows and the tearing away of these surfaces, which causes the phenomenon of erosion, will therefore take place when the rolling point has been passed.

Mr. Lanchester is disposed to think that the remedy lies in the use of high carbon in the steel, obtained either by carbonizing or by providing it in the stock. Where heavy loads are carried seizure can generally be successfully obviated by the use of well hardened steel. In a high duty gear box the elasticity of the gears and the individual teeth is so great that arguments based on the assumption of complete rigidity are of no weight.

In Fig. 1 herewith the sectioned area represents a small particle of the gear B torn out, and the blackened area the consequent groove. Fig. 2 illustrates the incipient stage of erosion and Fig. 3 the advanced stage.

## The Highway's Chief Enemy

**A**N interesting statement was made recently by J. N. Mackall, Chairman of the Maryland Highway Commission, in answer to a challenge from a truck manufacturer as to his evidence that the heavy truck destroyed his highways during the war. Mackall, in answer, said that his only evidence was that during the war unlimited loads were permitted on Maryland highways between Washington and Philadelphia and the highways were broken down. After the war, regulations as to weights and overloading were changed and the resurfaced highways had stood the test. Thus, he has removed one cause of failure and the roads have withstood the wear.

In a later statement Mackall revised this viewpoint somewhat and made a statement that brought nods of approval from all his auditors. Without a promise that his words are quoted exactly, his statement was like this:

"We have heard much recently about the effect of sprung and unsprung weights on the highways. I believe there is something in this, but I want to say

that while I believe the five-ton truck, weighing a total of ten tons, with half of the weight unsprung, does damage to the roads, I believe that the greatest enemy of the highway is the two-ton truck, carrying a load of five tons with the entire seven tons unsprung."

The manufacturers then had something to say about the damage to the truck that was carrying this excess load. They agreed that the overload was the cause of greatest damage to both truck and highway.

## 40 or More Miles Per Gallon

**W**HENEVER high efficiency is of paramount importance a powerplant is operated with the best possible load factor that is as near as possible to the load at which maximum thermal efficiency is secured. This is the condition which controls operation of most large powerplants, but it is unfortunately a condition seldom realized in the average automotive powerplant.

The cycle employed in practically all automotive engines is a cycle of high efficiency when a reasonably high compression ratio is employed, providing the engine is run at or near full load. Under these conditions a well designed engine will consume from about 0.5 to 0.6 lb. of gasoline per b.hp.hr. When, however, such an engine runs at light load—the condition which applies during perhaps 90 per cent of the time the average passenger car is running—the consumption per b.hp. will nearly or more than double, due in part to the low mean pressures developed as a result of throttling, and in part to the fact that pumping and other friction losses are approximately the same at a given engine speed whether the load is high or low.

This being the case it is evident that car operating conditions can be improved by at least two methods: by resorting to means for maintaining a constant compression regardless of load or by so arranging the transmission system as to enable the engine to run always at or near full load.

We have discussed the first of these methods in recent editorials. The second method is also worthy of careful study. It will, of course, involve the use of higher gear ratios, and unless changes in transmission design are made, more frequent gear changes than the average American car user is accustomed to, or, according to some persons who are presumed to know the demands of the buying public, willing to use. Theoretically it is possible to design a transmission which will enable, or even automatically compel, the driver to operate the engine at or near full load. Just how practicable a mechanism this would involve remains to be seen, but the possibilities of benefit from an economy standpoint are sufficient to make serious efforts in this direction very much worth while.

One engineer who appreciates the possibilities in this direction fitted to a well known make of car gears which give a 2.5 to 1 reduction as against the standard reduction normally furnished with this car, about 4.8 to 1. The fuel consumption fell from about 28 to approximately 43 miles per gallon. The car is, of course, less convenient to handle, but the owner con-

siders the saving worth the slight inconvenience, and we believe there are a great many owners in precisely the same class.

Be this as it may, it would seem to be no very difficult engineering problem to secure the advantages which are manifestly possible, without either serious inconvenience or undue mechanical complication. We believe the day is not far distant when some progressive manufacturer will reap a well earned reward by putting on the market in advance of less progressive makers a car which will not depart radically in general type, performance or size from the average car of to-day, but which will be capable of traveling in average use fully 40 miles per gallon of fuel. It is quite within the realm of possibility, and to say the least is a contingency which every car manufacturer should be in a position to meet.

## Rejuvenating Old Cars by Grinding

THE grinding machine industry recently has been putting considerable effort into the development of machines for regrinding various wearing parts of automobiles. It is claimed by some that by regrinding all the major wearing parts, the engine at least can be put into a better operating condition than it was in originally. This claim is based on the fact that after an engine has been used for a couple of years and subjected numerous times to both the maximum operating temperature and the lowest atmospheric temperature, its castings have attained a state of molecular equilibrium, and consequently there will be no further distortion. The claim might be disputed on the ground that not all the wearing surfaces of the engine will be ground, and that those bearings or joints which are not refitted will be more or less loose and therefore noisy. At the same time it must be admitted that the engine can be put back in a very good working condition, and there is no doubt that complete overhauling of engines, in which process grinding will play a prominent part, will become more popular in the future than it has been in the past. This will react on the automobile industry in two ways.

Regrinding the cylinder bores, fitting new over-size pistons and rings, and refitting the piston pin, crankpin and crankshaft main bearings will undoubtedly serve to restore the power and fuel economy of the engine, and thus to increase the value of the engine to the user. The latter will not only get better service from the car at less running expense, but the car will last him for a longer period and thus prove a better economic investment. By thus reducing the cost of automobile service the possible field of the automobile will be widened. On the other hand, if cars last for a longer period, the proportion of the machines in use that is scrapped each year will be reduced. While this might be regarded as a loss to the industry, it is hardly to be compared to the gain resulting from the more extensive use of the vehicles consequent upon the lessening of the operating cost as outlined above. Improvements in the methods of

maintaining motor vehicles in a good serviceable condition strengthen the economic foundation of the industry and should therefore be welcomed.

## Dr. P. P. Claxton

IN the retirement from office of Dr. P. P. Claxton, former U. S. Commissioner of Education, the automotive industry has seen the official passing of a firm friend. Dr. Claxton viewed, privately and officially, the automotive vehicle as a great transportation unit, one in which there were great social and industrial possibilities. He regarded the automotive vehicle as a means to better and more education and used his official position to make effective that view. He was particularly active in advocating the automotive bus as a means of promoting the long-needed consolidated schools in the rural district. Also he gave credit to the automotive vehicle for the promotion of good roads, which he regarded as one of the greatest educative steps of the last score of years.

His greatest work for the industry, and he regards this step as one of his chief accomplishments from an educational point of view, was his service in injecting into the school systems of the country the study of transportation and of traffic. He strongly supported the movement for traffic safety education in all schools and of studies that gave the pupil an appreciation of transportation at an early age, with a proper development of this subject through the advanced studies.

Dr. Claxton becomes Provost of the University of Alabama, located in a State which stands at the bottom of the list in automotive ownership. It is to be hoped that he will avail himself of his automotive knowledge as an aid in promoting education in that State. Also it is hoped that his official successor will continue the educational work he so well began.

## A Good Man for a Good Job

THE Society of Automotive Engineers is to be complimented upon being able to secure so excellent a man as Dr. H. C. Dickinson of the Bureau of Standards to act as manager of its new research department. There are few men with such a fund of information or so keen an appreciation of the value of research, and especially of fundamentals upon which all sound research work must be based.

It is to be hoped that the industry will lend its hearty co-operation in formulating and carrying through the research program decided upon, for the success of the whole venture is dependent upon a readiness to co-operate. In so doing what is given will be repaid a thousand fold in returns ultimately received.

Much commercial development work is now wrongly termed research. Such work is important but is to a large extent outside the field of activity to be fostered by the S. A. E. Sound development is, however, based upon sound fundamentals, and there is real need for gathering and disseminating the fundamental information which is to be sought in the new undertaking.

# Future Sales Prospect Brightens

## Hot Weather Decline Is Not Significant

Better Business in Farm States  
Probable With New Harvests  
—Conditions Sound

By JAMES C. DALTON

NEW YORK, Aug. 1—The inevitable summer slump in the sale of automobiles has begun in scattered sections of the country and will be reflected in curtailed factory operations. The surprising feature of the situation is not that the slump has come, but that it has been delayed so long. Seldom, if ever before, have July sales compared so favorably with those of preceding months. In many cities they surpassed the June totals, which probably is unprecedented.

A few of the factories have orders on hand which will keep them going at the present pace through August, and dealers in the most popular lines are several weeks behind on deliveries. Ford proposes the largest output in his history for August. In few cases have sales dropped back to the levels of May.

The future is in the lap of the gods. After periods of prolonged depression predictions are unsafe, but there is every present indication that there will be a revival in the automotive industry by mid-September. It will not be a boom, and that is fortunate, for most business men have learned to their sorrow that a period of unexampled prosperity is inevitably followed by a period of unexampled depression.

### See Substantial Revival

There are many reasons to believe, however, that the revival will be of substantial proportions and that sales will steadily increase in volume except for periodical depressions in the curve. Motor car sales in the future will depend more than in the past on general business conditions. Fundamentally, conditions are sounder than they have been in a year and a half.

Railroads and steel are barometers of general conditions. The carriers are doing better and the \$500,000,000 they soon will receive from the Government is provided with the distinct understanding that the major portion of it will be used in the purchase of needed supplies. This will give added impetus to the steel and iron trade which already shows slight improvement with lower prices.

Analysis of automobile sales for the first half of the year shows that they have been chiefly in the industrial states. There probably will be a falling off in these states for the last six months, but there is substantial reason to hope that this decline will be more than counter-

balanced by increased business in the great agricultural areas.

As a matter of fact, the outlook for the farmer is brighter than it has been since the collapse in the prices of farm products. He has been thoroughly "liquidated," but the sharpest edge of his grouse against the world has worn off. He is approaching a frame of mind where he will be willing to buy.

Crops of all kinds promise well and further declines in prices to the farmer are highly unlikely. Because of the general drought in Europe export demand is certain to be larger than it has been in many months. Exports of grain the first five months of this year were 60 per cent greater than for the same period in 1920 and were equal to a whole year's exports in the pre-war period. Exports of dairy products in 1920 were eight times as great as in pre-war years.

Increasing farm operations have relieved unemployment in many of the agricultural states. Except in the South, the unfavorable balance between agricultural and manufacturing districts is disappearing. Full harvests, plenty of farm work and substantial wage payments are stimulating business in Kansas and other early wheat states. Nothing resembling normal business can be expected in the farm states in the fall, but there will be a marked improvement in Kansas, Nebraska, Iowa, Missouri, Minnesota and the Dakotas.

### South Gains for Fall

There will be some improvement in the South, but it will not be so marked. Cotton prices must recover sharply before sales in this section show much gain. Little improvement can be expected in the stock-raising, mining and lumbering states, although they undoubtedly have seen the worst of their depression. Fall probably will bring a strong upward trend in wool prices.

California continues, generally speaking, to offer the least sales resistance, but there are indications it is reaching the liquidating point. Other sections which offer fair promise for sales are New England, with the exception of Connecticut, New York, Pennsylvania, Indiana, Wisconsin and Chicago. May sales of general merchandise also were good in Arizona, Maryland, Nevada, some parts of Texas, West Virginia and Wyoming. There are some bright spots in almost every state, even in the South, which can be studied with advantage by sales managers.

The long swing of credit conditions will be toward further easing, but the season for crop moving is approaching and this seasonal demand upon bank resources will have tendency to tighten loans temporarily except in the agricultural districts. When the new crops

(Continued on page 244)

## Reserve Bank Lauds Trade's Initiative

Cleveland Financial Institution  
in Statement Pays Compliment  
to Automotive Industry

CLEVELAND, Aug. 3—After stating that certain interests are holding business improvement back by failing to reduce living costs, the Fourth Federal Reserve Bank of this city pays a compliment to the automobile industry for reducing prices.

"It looks as if we are traveling in a helpless circle," reads the bank statement, "but the action of certain automobile makers in the recent past casts considerable light on the subject. Instead of hanging back and complaining that the other fellow was to blame, they reduced the prices of their products and convinced prospective buyers that they meant business. The theory that the man who has nerve enough to cut his prices regardless of what others are doing will get the trade, was proven correct by the increase in orders. And this same theory could be used to good advantage in practically all lines which are responsible for the present high cost of living."

Continuing the report states that mid-season depression still has the upper hand in most lines of business. Business about holding its own appears to fit the situation.

There appears to be a little better feeling in the passenger automobile line as compared to last month, and some good effects have resulted from the many price cuts. Some improvement is noticeable in the country districts where business has been very quiet for some time past.

The market for motor trucks is reported somewhat firmer. One large truck manufacturer reports sales as running a trifle over 50 per cent of last year.

### Atlanta Is Optimistic

ATLANTA, GA., Aug. 3—Business, industrial and economic conditions in the southeast are more nearly normal today than they have been at any time since the armistice, and business generally is on a sounder basis, according to the monthly report of the Federal Reserve Bank of Atlanta, published the latter part of July, and covering general business conditions throughout the sixth Federal Reserve district.

Investigation of the records of licenses issued during July and of transfers of licenses, at the office of the Secretary of State in Atlanta, indicates that auto-

# Bill Calls for Federal Motor Tax

## Measure Carries Out Treasury's Proposal

N. J. Representative Also Considers Reciprocal Proposals of N. A. C. C. and the A. A. A.

WASHINGTON, Aug. 2.—Congressman Appleby, of New Jersey, has introduced a bill providing for a special license tax on automobiles and for a Federal license tax for motorists. The broad principle of his bill is in line with the proposal of the Treasury Department that a Federal license tax should be imposed as a part of the internal revenue bill. A reciprocal feature would carry out the principles for which the National Automobile Chamber of Commerce and the American Automobile Association and other automobile organizations have sought in a legislative manner.

### No Estimate Made

In an interview with AUTOMOTIVE INDUSTRIES, Congressman Appleby today said that he had not estimated the probable revenue that would accrue from the license tax. He appeared before the House Committee on Ways and Means and explained his bill today.

Ninety per cent of the revenue derived from the licenses would go to the Federal Government and 10 per cent to the State. The rate as proposed by the Appleby bill would be forty cents per horse-power or a fraction thereof in the case of all vehicles having pneumatic tires, with a minimum charge of \$5 for any motor vehicle.

For each motor vehicle equipped with solid tires and having a rated carrying capacity of not more than one ton, the rate would be \$10, and \$10 for each additional ton up to 7 tons, when the Federal rate would be \$70. Motorcycles would be obliged to pay \$3 per year, with an additional tax of \$1.50 for each side-car.

Manufacturers of or dealers in motor vehicles other than motorcycles would be obliged to pay \$3 for each registration tag, and registration tags would be interchangeable among the cars owned or used by such manufacturers or dealers during the current year for which the tax is issued, and would be allowed to be used only on new vehicles being brought under their own power from a factory to a dealer.

It is further provided that "no such dealers' tags shall be used on any car employed in transportation for hire or livery business. For each registration tax issued a dealer in motorcycles, \$1.50, such tags to be interchangeable as in case of dealers in other motor vehicles. For each rubber-tired vehicle with a carrying capacity of one ton or less, trailed

or propelled by any motor vehicle on which a Federal license is required to be displayed, \$5; and \$5 additional for each additional ton of carrying capacity or fraction thereof."

It is significant to note that the Appleby bill provides that the charges which it prescribes shall be for the twelve months period, "and shall in no way conflict or interfere with the license fees imposed by the respective States."

The administration of this proposed Act would be vested in the Bureau of Public Roads, after authority had been conferred upon it to negotiate with motor commissioners of the various States. The penalizing provisions of the bill call for a fine of not less than \$50 nor more than \$200, when any person operates an automobile without a Federal license. A Federal license is not obtainable until the State authorities have been convinced that the applicant for a license

(Continued on page 246)

## Staff of Class Journal Bids Sherman 'Au Revoir'

NEW YORK, July 28.—The staff of the Class Journal Co. gave a farewell luncheon at the Woodstock to-day to Ray W. Sherman, executive editor, who has resigned to become merchandising director of the Automotive Equipment Association. Sherman was presented with a handsome watch as a mark of esteem.

David Beecroft, directing editor of the Class Journal publications, presided. He praised highly the work done by Sherman in building up Motor World, with which he was connected for more than seven years. An address of similar purport was made by H. M. Swetland, president of the United Publishers Corp. and the Class Journal Co.

The presentation of the watch was made by Neal G. Adair, editor of Motor World.

Sherman will leave for Chicago tomorrow with his family to take up his new work immediately.

## 500 Buy Durant Stock in Lansing Territory

LANSING, MICH., Aug. 1.—More than 500 persons in Lansing and vicinity have purchased stock in the Durant Motors, Inc. Stock sales have exceeded 6,000 shares.

This was announced Thursday morning by G. N. Murchey & Co., local Durant representatives. Most purchases have been in 10, 15 and 20 share lots, Glenn Murchey stated Thursday. The recent statement by the corporation that no more than 20 shares may be purchased at one time on the Durant partial payment plan has not apparently retarded sales.

## Bosch Magneto Head in U.S. to Fight Sale

Otto Heins Here to Press Suit to Have Auction by Palmer Declared Void

NEW YORK, Aug. 1.—Otto Heins, former president of the Bosch Magneto Co., has arrived in this country from Germany to press his suit to have the sale of that property declared void. It recently was charged that A. Mitchell Palmer as alien property custodian showed undue favoritism to the present owners in the sale of the assets at auction.

Heins is represented by his attorney, Harvey P. Andrews of this city, who also is acting for several other German interests which are seeking the return of the property they formerly owned. Associated with him in this work are Clarence D. Miller, secretary of the Republican National committee and John Thomas Taylor, head of the Washington office of the American Legion, according to a statement by Andrews. Andrews has had much correspondence with the Republican senators and representatives who are members of the Foreign Relations committees of the two houses of Congress. Andrews himself has been prominent in Republican politics in this city.

Heins, who is a German citizen but is said never to have been declared an enemy alien, returned to Germany early in 1920, having been reduced from the status of a millionaire almost to that of a pauper. He has completed the reorganization of his business interests in Germany and has visited England, France and other countries. He now has come to the United States to make a strong effort to regain control of the company now known as the American Bosch Magneto Corp.

### Will Go Into Business

Regardless of the success of his suit, Heins intends to go into business in competition with the American Bosch Magneto Corp., according to Andrews, "and expects to surpass them all in the manufacture of magnetos." His attorney added that he expects to file patents very soon and will manufacture a new spark plug and lighting system.

The action started against Palmer on behalf of Heins over the sale of the Bosch Magneto Co. alleges fraud and demands that the sale be declared null and void. It is charged that Palmer sold the property to Martin E. Kern, a personal friend, for \$4,500,000, although it was worth \$12,000,000.

## Many Resignations Follow Goodyear Cut

**Sweeping Salary Reductions  
Cause Break in Personnel—  
Budget System in Force**

AKRON, Aug. 1.—With all office and factory departments of the Goodyear Tire & Rubber Co. placed on a budget system effective Aug. 1 under the new financial control of the company, sweeping salary reductions have been made in the offices in addition to reductions in office personnel. In order to keep each department within its respective budget, many departments have cut personnel over 10 per cent, while all departments have reduced salaries from 10 per cent to 20 per cent under the budget paring.

The readjustment of office personnel at Goodyear has resulted in the resignations this week of some of the company's oldest officials and employees, including George Rogers, in charge of credits and collections, who has been with Goodyear for 20 years. He was one of the first associates of F. A. Seiberling when Goodyear, then two years old, was struggling for a foothold in the rubber industry.

### Assistant Treasurer Out

Other resignations announced include those of Harry Blackburn, assistant treasurer; Marshall Morris, formerly assistant general manager of the Goodyear Co. in California and more recently in charge of the new stock issues under the refinancing program; F. F. Dugan, in charge of sales personnel; Don Stevens, in charge of the factory labor department, and Dr. Clyde Leeper, medical officer in charge of the office dispensaries and nurses' staff.

W. D. Shilts, chairman of the board of control under the Seiberling régime, which was abolished when E. G. Wilmer succeeded Seiberling as president, has been assigned to install the budget system in Goodyear branches and to reduce expenses in all branch offices. C. C. Prather, manager of the products department, has been transferred to the sales department and assigned to Cincinnati as a general line salesman. C. T. Crudginton, editor of the *Goodyear Tire News*, and lately assigned to Council Bluffs, Iowa, as a general line salesman, has resigned and returned to the East.

### PLAN TRACTOR FIELD SHOW

MONMOUTH, ILL., Aug. 2.—Tractor dealers are co-operating with the Chamber of Commerce, the farm bureau and local farmers in arranging a field demonstration Aug. 11. It is probable that the program will require two days and committees are completing outline of the field work.

To emphasize the value of power farming, teams of horses will be employed on adjoining fields to demonstrate the greater efficiency of the tractor operated machine.

### GRAND CENTRAL PALACE SCENE OF 1922 SHOW IN NEW YORK

NEW YORK, Aug. 2.—Definite announcement is made by the National Automobile Chamber of Commerce that the annual New York show will be held at the Grand Central Palace Jan. 7-14. Earlier in the year it was supposed the Palace would not be available and Madison Square Garden was the next best location. Plans for converting the Palace into offices have been delayed, however, and the N. A. C. C. will be able to use it for the 1922 exposition which will be one of the most important ever held.

## Surplus Truck Sale Will Be Continued

WASHINGTON, Aug. 2.—All surplus property of the War Department scheduled for sale during August will be disposed of as previously arranged and unserviceable motor vehicles will be sold wherever possible. This policy was determined upon to-day following a conference between Director of Budget Dawes, Assistant Secretary of War Wainwright and Col. Hartshorn, Director of Sales, War Department. Director of the Budget agreed to the plan after learning that the War Department had canvassed other branches of the Government again and given them an opportunity to make requisition for surplus stocks held by the War Department, thus meeting the requirements of recent order from the Director of the Budget. This agreement between Government officials, now applicable for August only, is expected to be extended and other stocks probably will be sold when it is shown that other departments have been given opportunity to make requisition on War Department material.

## Several Changes Made in Personnel of G. M.

NEW YORK, Aug. 1.—General Motors Corp. announces the following assignment of duties and changes in personnel in the central office, Detroit:

James McEvoy has been appointed to the Advisory Staff, in charge of legal matters under the general counsel. J. G. Stevenson will be associated with McEvoy in legal matters.

A. C. Anderson, assistant comptroller, will be in charge of matters relating to insurance.

C. E. Stowe, assistant treasurer, will be in charge of matters relating to employees' fidelity bonds.

H. W. Webster, of the treasurer's department will be in charge of matters relating to taxes other than Federal taxes.

L. B. Robertson, in charge of taxes and insurance, has resigned.

## Fisk Stockholders to Readjust Capital

**Will Change Par Value of Common Stock from \$25 to No Par  
—Will Buy Federal**

NEW YORK, Aug. 2.—Stockholders of the Fisk Rubber Co. will meet Aug. 9 to act upon a readjustment of the capital stock and debt of the corporation and to change the par value of the common stock from \$25 a share to no par. The proposals under the plan provide for the creation of bonds without limitation on maturity and the creation of a class of stock with voting rights superior to any now outstanding. In addition, authorization will be asked for the creation of one or more mortgages to secure the bonds. Another proposal is to acquire the assets and the liabilities of the Federal Rubber Co. and the Ninigret Co.

The Fisk Rubber Co. is controlled by John N. Willys personally and not by the corporations of which he is the head. The Fisk company in 1915 acquired control of the Federal Rubber Mfg. Co., which was succeeded by the Federal Rubber Co. It owns \$2,550,000 of the \$5,000,000 common stock of the Federal company. The Ninigret company is a Rhode Island corporation with a capital of \$550,000, with mills at Westerly in which all kinds of textile fabrics, including automobile tire fabrics, are manufactured.

### \$8,500,000 from Surplus

In a letter to Fisk stockholders outlining the situation, it is stated that inventory adjustments resulted in a deduction of about \$8,500,000 from the surplus accounts, so that the balance sheet now shows a deficit. Thus far this year Fisk has accepted nearly two-thirds of the rubber and fabric for which it was committed. While prospects for earnings and for a substantial reduction of the debt are excellent, Fisk and Federal will remain dependent upon bank loans for a large amount of working capital.

The plan calls for a bond issue to the amount of \$10,000,000. Stockholders in the Federal Rubber would receive first preferred stock of Fisk, share for share, and in addition 58 2/3c. a share as a dividend adjustment. Holders of Ninigret stock would receive in exchange common stock of Fisk.

### WAINWRIGHT RUNNING AT TOP

CONNEERSVILLE, IND., Aug. 3.—The Wainwright Engineering Corp. is running its plant at full capacity on the day shift and 50 per cent at night, turning out 3600 pistons a day, chiefly for the jobbing trade.

John D. Carmody, for the past seven years district manager for the Champion Spark Plug Co. has been appointed Pacific Coast manager for the Wainwright company, with headquarters at San Francisco.

## Interlocking Cord Receiver to Go Soon

**If Stockholders Raise \$20,000  
Fund Receivership Will End  
in 30 Days**

AKRON, Aug. 3.—The receivership of the Interlocking Cord Tire Co., of Akron and Mogadore, will be lifted within 30 days, conditional upon the raising among stockholders of a fund of \$20,000 to pay part of the company's claims in cash and to make a 15 per cent payment on the balance, according to an agreement entered into by officials of the company with receiver Elihu Harpham and Judge W. J. Ahern of Common Pleas Court.

The receivership was created last January upon indictment of officers of the company for alleged violation of the Ohio Blue Sky Laws. New officers elected since then are Edward Kohl, president; W. B. Smith, vice-president; R. E. Cartledge, treasurer, and R. A. Rukamp, secretary.

Claims against the company total approximately \$80,000, including general claims of \$35,000, preferred accounts of \$45,000, work and labor claims of \$1,300, and attorney and receiver fees of \$12,500, in addition to \$1,200 owed the Ohio Industrial Commission and \$5,000 owed the Government in excise tax and penalties. Under the agreement entered into a mortgage on the company's property will be executed and delivered to the Ohio Savings & Trust Co. to secure these claims. Stockholders will be asked to raise \$20,000 to make full cash payment of the claims of the Government, Ohio Industrial Commission, attorneys and receiver, and the work and labor items, and also to make a 15 per cent payment on the \$60,000 balance. The preferred balance is to be paid in one year, and the balance due on general claims will be payable in full within two years.

Stockholders already have paid in over \$15,000 towards the fund, which will mean lifting of the receivership. The company expects to get back into production with 30 days, with the Akron Engineering Co. handling all production. Suits filed by the receiver for collection of nearly \$200,000 in unpaid stock subscriptions will not be prosecuted for the time being, pending the lifting of the receivership.

The indictments against former officers of the company are still alive in the Common Pleas Court of Akron.

### WINTER CHANGES NAME

DOVER, DEL., Aug. 3.—The Winther Motor Truck Co. has filed a certificate changing its name to Winther Motors, Inc., and announcing that its capital has been increased from \$22,000,000 to \$61,000,000. The Kenosha Wheel & Axle Co. and the Marwin Truck Co. recently were consolidated with the Winther company.

### JIMMY MURPHY FACED DEATH IN PRACTICE BEFORE GRAND PRIX

NEW YORK, Aug. 1.—Friends of Jimmy Murphy, who won the French Grand Prix at Le Mans in a Duesenberg car on July 25, are convinced he is a favorite of fortune. They are talking about his remarkable escape from injury in practice prior to the race when his car turned over while he was trying to avoid running down a horse which had strayed on the road. Louis Inghibert, who was serving as mechanic, was taken to a hospital with three broken ribs and was unable to take part in the race, but Murphy escaped without a scratch and his car was not damaged.

## Farmers and Labor Open Fight Against New Roads

TOLEDO, Aug. 3.—Organized farmers and labor of Ohio have begun a fight against the carrying out of the road construction contracts let by the State Highway Department, which provide for the building of nearly 100 miles of new highway with an expenditure of nearly \$3,000,000. The contracts have had included in their provisions an agreement that any lowering of freight rates will result to the benefit of the state.

But even though the contracts place the cost per mile about \$36,000 as an average for all kinds of improved roads, the labor organizations say that that figure does not represent the decrease in wages taken by labor this summer and the farmers declare that under any circumstances the road building at that cost must await the return to normal. They point out that the same roads were built before the war for \$10,000 a mile.

It is doubtful whether the road-building campaign will be interfered with this summer, as the contracts have been legally let. However, the result of the agitation may be to suspend contemplated projects next summer.

### CANADA'S EXPORTS INCREASE

OTTAWA, ONT., Aug. 3.—Canadian motor cars, chassis and parts exported to Australia during the fiscal year 1919-1920 amounted to a value of \$2,308,360 an increase of \$372,535 over the figures for the year previous, thus giving Canada second place in the list. America being first and United Kingdom third.

### MAINE AFTER HEAVY TRUCKS

BOSTON, MASS., Aug. 3.—Maine has started a campaign to rule off the highways trucks exceeding the 18,000 pound limit law passed by the last legislature. It will particularly affect commercial vehicles carrying loads from Massachusetts into Maine, if the campaign is effective.

## Studebaker Income Shows Healthy Gain

**Net Profits Three Months Ending  
June 30 Come to \$4,270,547  
Report Says**

SOUTH BEND, IND., Aug. 1.—The Studebaker Corp. for the three months ended June 30 reports net income of \$4,270,547 after all charges and reserves for inventory adjustment. After payment of preferred dividends this was equivalent to \$6.83 a share on the outstanding common. In the first three months of the year the company reported net profits of \$2,210,577.

Net sales for the second quarter of 1921 were \$33,059,834, as compared with \$22,249,299 for the same period in 1920. Total assets are \$96,880,381, including trade name and good will, which are valued at \$19,807,277. Inventories amount to \$20,926,304, cash to \$6,376,030, sight drafts to \$3,318,068 and accounts and notes receivable to \$5,879,734.

The company has no notes payable and accounts payable amount to only \$3,892,413. Miscellaneous liabilities are listed at \$3,165,772 and the reserve for Federal taxes at \$2,617,023. There is a special surplus account of \$3,645,000 and the regular surplus stands at \$13,760,000.

Production of cars in the quarter ended June 30 reached 8498, as compared with 4811 in the same quarter last year.

The directors have declared the regular quarterly dividends on the preferred and common stocks.

## Threefold Demand For Endurance Race Meets

SAN FRANCISCO, CAL., Aug. 2.—Public demand, met more than half way by the desire of the manufacturer and the distributor, seems to be bringing back the old-time demonstration and endurance races, designed to show exactly what each car will do. The object of these races, of course, is twofold, first to bring home to the public mind the performing ability of the automobile, especially the stock car, and, second, stimulate improvements in construction and mechanical design. On the Pacific coast there also is manifest an appreciable revival in interest in the racing game, and large crowds greeted the finishes of the races at Tacoma, Seattle, and Reno this year.

### TIMKEN LAYS MEN OFF

COLUMBUS, Aug. 2.—A slight depression in business has caused a lay-off of a number of men at the Columbus plant of the Timken Roller Bearing Co. Since the plant resumed operations gradual increase in the working force has been made until approximately 400 men were employed. The depression is expected to be temporary and men will be put back at work as soon as things improve.

## Dr. Dickinson Heads Research Bureau

**Quits Work with Bureau of  
Standards to Assume New  
Duties with S. A. E.**

NEW YORK, Aug. 1.—Dr. H. C. Dickinson, who has been assisting Dr. S. W. Stratton, Director of the Bureau of Standards, Washington, D. C., has been engaged by the Society of Automotive Engineers to manage the research department which was created by the Council of the society at its February meeting in Chicago. Dr. Dickinson will assume his new duties on Sept. 1, after which date he will be located in this city.

For some months the council of the society has been carrying on its efforts to secure Dr. Dickinson, but his work in connection with the Bureau of Standards has been of such importance that it was only after repeated presentations of the case that Dr. Stratton consented to grant the necessary release. Dr. Dickinson's work with the Bureau of Standards has been very closely connected with the automotive industries in that this phase of research work in the bureau has for some years come directly under his control. No one better qualified to handle the research program of the society could have been secured. He has a mind peculiarly trained for research work. His coming with the S. A. E. assures the success of the research program.

### Presents His Views

In the August issue of the *Journal of the Society of Automotive Engineers*, Dr. Dickinson presents some of his views on the subject of research. He classes research under three heads:

- 1—Explorational research.
- 2—Intensive research.
- 3—Developmental research.

**Explorational research.**—This research deals with the fundamental analysis of problems through the study of available literature, and of the technical and economic condition involved.

**Intensive research.**—This includes the major part of research usually accomplished in experimental research laboratories. It requires considerable laboratory equipment.

**Developmental research.**—Developmental research involves the application of experimental facts and principles to the solution of practical problems. It seldom leads to the highest efficiency and never to a knowledge of principles. It is the method of evolution, as well as that by which practically all of the mechanical arts have received their initial development.

Dr. Dickinson believes the aims of the research department of the Society of Automotive Engineers for the immediate future are to encourage and secure as far as possible a more systematic survey of the research field as applied to our

### FIGHT ON GEORGIA GAS TAX WON BY AUTOMOBILE DEALERS

ATLANTA, GA., Aug. 2.—Contrary to expectations the bill before the Georgia State Legislature providing for a one cent per gallon retail sales tax on gasoline has been defeated. Automobile dealers bitterly opposed the bill, not so much because of the additional one cent per gallon they would have to add to the price of gas, but because of the extra amount of book-keeping such a law would compel.

industry, to bring to the attention of the various laboratories such problems as appear in most pressing need of solution or of increased attention, and to secure to the greatest extent feasible a more general interchange of information between the various laboratories and individual investigators.

In carrying out this work, Dr. Dickinson believes it necessary to draw a sharp line of distinction between developmental research and fundamental or intensive research. Developmental research must be considered of a private and confidential nature; whereas intensive research is distinctly of more value, if mutually shared by the members of the industry.

Dr. Dickinson proposes to use existing laboratories to the fullest extent. In this work there are three types of laboratories to be utilized:

- 1—Corporation laboratories.
- 2—Educational institution laboratories.
- 3—Government laboratories.

Each should be occupied with the kind of problems with which it is best fitted to deal. There are many corporation or industrial laboratories that have excellent material facilities, and able men, but are doing little that can properly be classified as research work.

The laboratories of educational institutions require a closer contact with the problems and requirements of industry. The Government laboratories have inadequate contact with industries and do not always appreciate the relative importance of various problems.

### FORM DISCOUNT COMPANY

QUINCY, ILL., Aug. 3.—The General Discount Corp. has been issued incorporation papers in Springfield with a capital stock of \$225,000. Rolland M. Wagner, Arnold V. Scott and C. B. Parks are incorporators.

The firm will make loans from its capital upon automobiles, deal in automobile dealers' notes, conduct rediscount business on contracts and handle mortgages. Scott, the manager, has been associated with the State Savings Loan & Trust Co., but is resigning to devote his entire time to the new organization. A. E. Gibson will be fiscal agent for the company.

## 45,000 Less Employed in Akron Tire Plants

**Records Show Drop from 72,000  
in Spring of 1920 to 27,000  
with Production 80%**

AKRON, Aug. 1.—Employment records from the nine major rubber companies in Akron show that between 26,000 and 27,000 day workers and tire builders now are being employed as compared with about 72,000 in the same factories during the peak months of the tire industry in the spring of 1920. The low ebb of employment is reported to have been slightly under 19,000 factory workers in December of last year and January of this year. The records apply only to day workers and not to office employees or salaried factory employees.

The employment figures are regarded as significant in view of the fact that these same nine rubber companies are producing over 80 per cent of their peak production of 1920. This indicates over 80 per cent of peak production with 36 per cent of peak employees, showing a high percentage of increased efficiency both individual and collective among factory workers.

For example, the Goodyear company when it had a peak production of 31,181 tires daily had nearly 33,000 employees on its payroll, including its office personnel. To-day Goodyear is producing 28,640 tires with about 13,000 employees.

The employment figures cover the Goodyear, Goodrich, Firestone, Miller, Kelly-Springfield, Swinehart, Star, General and Mohawk factories in Akron.

## Freight Barge Fleet to be Operated by Ford

NEW YORK, Aug. 1.—Henry Ford is preparing to put into operation at an early date a fleet of freight barges to transport automobile material from Detroit, via the Erie Canal, to Troy and this city. The barges have been planned by Ford, and will be propelled by marine gas engines. They will be 150 feet in length and 20 feet in width, having a capacity for 1000 tons of freight.

The barge shipments, in addition to supplying the Kearney plant with material, will be used for shipping motor parts and freight to the Ford plant to be built at Troy. Work on the large power house there is now under way, but the factory will not be ready for operation until nearly a year hence.

### TRACTOR SALES GROWING

INDIANAPOLIS, Aug. 3.—Tractor business in this territory is picking up materially, branch managers here declare. They say the farmer is fast recovering from the shock of lower grain and live stock prices and is returning to the markets in a buying mood. Dealers here do not believe the price decreases will have merely a temporary effect in stimulating sales.

## Germany Goes After South African Trade

### Post-War Models Arrive in Johannesburg—Demonstrate Benz Models

JOHANNESBURG, June 28 (By Mail)—The first tank steamer carrying oil fuel in bulk has paid a visit to the newly completed storage tanks at Durban, Natal. For a considerable time the policy of importing oil fuel in bulk has been advocated and at several other ports the construction of large tanks now is being proceeded with.

More post-war German models have arrived. The Benz cars and trucks have been demonstrated in various parts of the country and consignments of Adler models are expected. Germany intends to capture part of the South African automobile trade and efforts are being made in different centers to popularize German automobiles.

The Vacuum Oil Co. has announced a reduction of two shillings current rate of exchange (40 cents) per case of 8 gallons in the wholesale price of petrol. This cut in price was not wholly unexpected but was welcome nevertheless. A consignment of power alcohol which is compounded with other substances and marketed under the name of Natalite, has been sent to England for demonstration and experimental purposes. It has been on the South African market for about four years and was widely used during the petrol shortage. The price is considerably less than that of petrol and the results given are considered excellent. The verdict of the English automobile bodies is being awaited with interest.

A number of price reductions in cars has been announced during this month, and Studebaker models are selling at very low prices indeed. The "Big Six" is now obtainable at \$2,887, whereas only six months ago it was selling for \$3,562. With these price reductions ruling the sales of English and Continental cars have become slower, as no reductions worth mentioning, with the exception of the Vauxhall, have been made.

Ralph Dort of the Dort Motor Car Co., has been touring S. A. studying trade conditions. This is the first occasion on which a principal of a large American motor manufacturing firm has visited this country. Dort motor cars are few and far between in Africa, but after Mr. Dort's visit it is expected agencies will be fixed up in various parts of the country.

The trade position still looks hopeful for the second half of the year, and the results given by the motor sections at the different Agricultural Shows held in the country districts give evidence that the farming community are open to buy automobiles if the territory is properly combed out. More intensive sales methods are being used with the result that in the spring the car business ought to be brighter.

### FRANKLIN EMPLOYEES DRINK 2,000 PINTS OF MILK EVERY DAY

SYRACUSE, Aug. 1—Employees of the Franklin Automobile Co. have become the champion milk drinkers of the city. The company has installed a refrigerating system and sells the milk at any time of the day. On one hot day recently 2500 pint bottles were sold and the usual daily consumption is 2000 pints. The proceeds from the sale of the milk are used for the support of the Franklin Employees band, numbering forty pieces.

### Company Is Organized to Take Over Root Firm

SPRINGFIELD, OHIO, Aug. 3—With a capital of \$300,000, the Automotive Supply Co. was organized to-day to take care of the wholesale business of the H. G. Root Co. J. L. Zismer was elected president and treasurer and L. W. Peaz, secretary. Besides these men the directors are H. G. Root, general manager of the Westcott Motor Car Co., J. Stanley Weigel and W. C. Webster. The new company will take over the wholesale business of the H. G. Root Co. Aug. 1.

Speaking of the new company Zismer said: "We will carry all kinds of auto supplies. Retail stand will be maintained as usual. We will operate the wholesale business in Springfield and Columbus and will develop this wholesale automotive supply business in this territory."

### Braender Rubber Has Reorganization Plan

NEW YORK, Aug. 2—The creditors' committee for the Braender Rubber & Tire Co. of Rutherford, N. J., which was thrown into bankruptcy in May, has worked out a plan for reorganization which has been submitted to creditors. It calls for the formation of a new company to take over the assets of the old and under the plan all creditors except the Braender family would take first preferred stock at par, equal to their claims. Claims less than \$100 would be paid in cash. Management and control of the business would be vested exclusively in the first preferred stock until all this class of stock had been retired out of earned surplus. By vote of holders of two-thirds of this stock the company could be liquidated at any time.

The total liabilities of the company are \$1,028,638. They are divided as follows: Federal taxes and wage claims, \$90,819; claims of creditors secured by collateral and indorsements of members of the Braender family, \$190,606; claims of general unsecured creditors, \$202,481; claims of members of the Braender family, \$369,731; claims for damages by unsecured contract creditors for undelivered merchandise, \$175,000.

## Italy Building New Motor Car Speedway

### Hope to Have Brescia Track Completed for Races September 4-11

MILAN, ITALY, July 20 (By Mail)—That Italy is determined to maintain the position it has occupied in the past in automobile road racing is established by the building of a special road-racing circuit in the form of an 11-mile triangle close to the town of Brescia where Italy's greatest road races have taken place in the past. The Automobile Club of Milan, with the aid of the citizens of Brescia will have this 11-mile racing triangle completed in time for the week of September 4-11, when a three-day program of motor races supplemented by an aviation program will take place.

The new Brescia circuit makes use of approximately 10 miles of existing highways and includes 1 mile of new highway built to avoid going through the town of Montichiari, which is the only town on the circuit. Two sides of the triangle are approximately 3½ miles straightaway. The new roadway being built over the entire 11 miles has a minimum width of 26 ft. and a maximum of 32½ ft. It is being macadamized and tarred throughout the complete length. Curves are being specially prepared for speed. One parabolic curve connecting the two 3½-mile straightaway sides is expected to admit of very high speed.

A complete equipment of grandstands, restaurants, press-stands with telegraph and telephone installations is being installed.

The program for the September week opens with the Grand Prize September 4, a 3-liter classification of thirty laps or approximately 324 miles.

On September 8 there will be the Grand Prize for light cars, 1½-liter piston displacement at 216 miles. On this day kilometer trials for all classifications will take place.

September 11 will be given over to the Grand Prize for gentlemen drivers in which engines of any capacity over 2 liters will be admitted. There will be three classifications in this event.

### NAME MONITOR RECEIVER

COLUMBUS, Aug. 2—Upon the application of the J. E. McNally Lumber Co. who held a note against the company, Judge Rogers in the Franklin County Courts has named Ernest W. Pavy, receiver for the Monitor Motor Car Co. under a \$50,000 bond. It is claimed that the company has a considerable amount of finished cars, partly finished cars and materials on hand and pressing creditors threaten a dissipation of the assets. The receiver has announced that the assets aggregate \$400,000 and the liabilities, \$190,000. Operations at the plant, outside of furnishing service, have been suspended.

## Big Labor Efficiency Increase for Willys

Production With 7700 Men 50 Cars Greater Than With 13,000 Year Ago

TOLEDO, Aug. 2—That the Willys-Overland plant is getting greater production today with 5,000 less employees than it did a year ago was the finding of President John N. Willys while here on a visit to the factory this last week.

Willys sent out some interesting information to the stockholders as a report of how he finds things here.

He said the company with 7,700 employees now is producing 50 cars more per day than a year ago when there were 13,000 men at work.

"You will be interested to learn that our business in the last two months has been very close to normal. June and July have averaged between 10,000 and 11,000 cars a month," the letter sent to all shareholders said.

"Since March I have talked to more than 2,500 of our dealers and distributors and I am pleased to state that since then we have added more than 400 to our dealers' list.

"I think you will agree that is very good under the distressing business conditions, which have been general all of this year.

"For the past 10 days I have been studying every detail of the business here, and I find the whole organization working thoroughly in harmony under the direction of C. B. Wilson, vice-president in charge of operation.

"A great many economies have been made and we are going to make a great many more. For instance, last week we made approximately 550 cars a day, which is about 50 cars more than a year ago, and the total number of factory employees at present is 7,700 as compared to 13,000 a year ago.

"This shows an increase in efficiency that is very gratifying."

Following in line with the reported decrease due for this month in the working force at the Overland other Toledo subsidiary plants were planning cuts in their forces.

The Electric Auto-Lite Corporation plans on operating through August with very little reduction in its force of 1300 employees. Possibly 100 will be let out.

The Overland is reducing its force gradually paring off a few hundred each week.

This week the company shipped several boatloads of cars to Buffalo.

### DENY RUTENBER CLOSING

INDIANAPOLIS, Aug. 3—In denial of the rumors circulated to the effect that the Rutenber Motor Co., at Marion, Ind., had discontinued business, R. S. Bower, general manager of the company, stated that such rumors are absolutely false. He says the Rutenber Motor Company is doing as much business

as the majority of the factories in Marion to-day, and that there has never been any ground for such statements. He said it was true that the company had sold their old factory to another company, but that they had immediately purchased another plant where they have since continued doing business.

## Preston Motors Brings on New Roadster Model

BIRMINGHAM, ALA., July 30—Preston Motors Corporation have recently brought out a roadster, a new model for 1922.

The roadster has the same chassis as the touring car, having a wheel base of 117 in., and the same standard units throughout that have featured the Premocar since it was first put on the market. The roadster has the same high, well-arched hood, streamline effect, with beveled edge and a sloping rear end, that makes its whole appearance quite attractive.

The seat is roomy and comfortable, and the doors are large. A noticeable feature is the rear compartment, which is unusually large. The lid lifts up and is held by side arms, uncovering a space large enough to carry a large size steamer trunk or all sorts of bags and baggage. The price of the roadster is the same as the touring model and production is now going on.

## Duesenberg Shipments Will Start September 1

INDIANAPOLIS, July 18—Deliveries to dealers who have been established in all parts of the country, will be begun Sept. 1 by the Duesenberg Automobile & Motor Co., Inc. Orders for more than 3,000 cars which will cost in excess of \$12,000,000 now are on the books.

Factory production will be in charge of A. W. King, formerly production manager for the Buick Motor Co. and the Northway Motors Co., who recently returned from France where he reorganized the production system of the Berliet company.

The sales organization is being perfected by Harry W. Anderson, who has served as sales manager for Stutz, Templar and the Buda Co.

### U. S. PRAISES N. A. C. C. IN WAR

NEW YORK, Aug. 1—The National Automobile Chamber of Commerce has been awarded a certificate of merit by the War Department in recognition of loyalty, energy and efficiency in the performance of its war work, which materially advanced the war program.

### FORD TRACTOR CUTS FORCE

HAMILTON, Aug. 2—C. A. Anderson, manager of the Ford Tractor plant announces that all but 75 men employed in the factory will be laid off July 30 until Aug. 15. This means that 325 men have been laid off until that time. No explanation for the action was made.

## Brazil Invites U. S. to Tractor Trials

Ministry Anxious for American Entries for Annual Meet at Praia Vermelha

NEW YORK, Aug. 3—The annual Brazilian tractor trials for 1921 will be held on Oct. 1 at Praia Vermelha, a suburb of the capital, Rio de Janeiro, under the auspices of the Brazilian Ministry of Agriculture. This information was contained in a cablegram from the ministry received to-day by EL AUTOMOVIL AMERICANO, the Spanish automotive publication of the Class Journal Co. Entries from American manufacturers are asked by the ministry which states that the trials will be similar to those held last year.

The 1920 competition was held early in October at Santa Cruz and Deodoro, also suburbs of the Brazilian capital, with entries of Twin-City, Allis-Chalmers, Monarch, Titan, Moline and Fiat tractors. A six-hour plowing match was held that was carefully observed by representatives of the ministry and a report was later made showing the cost and results as it applied to each entrant. The field chosen last year was not entirely suitable for satisfactory plowing as it had been deforested only a short time before the contest. Although today's cablegram did not mention this subject, from other correspondence it is believed the trials will be held this year in more suitable territory.

Conditions in Brazil, so far as they pertain to the automotive industry, are reported as showing much improvement, despite the fact that present exchange conditions make immediate business very difficult. Some American manufacturers, realizing that this condition is only temporary, have come to satisfactory arrangements with their Brazilian representatives and have made recent shipments of complete cars and trucks. Road building is continuing in Brazil and much new mileage is being gotten under way. The 107 kilometer road between Sao Paulo and Campinas, in the coffee country, has just been opened for traffic and is one of the numerous roads that are being put in first class condition.

### ACCESSORY MEN TO CONVENE

PHILADELPHIA, Aug. 1—The Automobile Accessories branch of the National Hardware Association will hold its fourth annual meeting and exhibition on Young's pier at Atlantic City, Oct. 19-22.

### DENIES FREIGHT RATE CUT

NEW HAVEN, CONN., Aug. 1—E. J. Pearson, president of the New York, New Haven & Hartford Railroad, denied to-day that there would be a general reduction in freight rates to meet the keen competition offered by motor trucks.

# Detroit Production Gained in July

## Output Increased in Most Factories

### Some Propose Continuance of Present Schedules This Month —Sales Holding Well

DETROIT, Aug. 2.—Production in a majority of Detroit plants for July shows a general increase over June and in some of them schedules for August indicate a continuance of the present output. The Ford Motor Co. closed the month with a total production of 107,132, about 5 to 6 per cent of which was trucks. This was slightly under the schedule outlined, due to manufacturing conditions only. In August the company is adhering to its 109,000 schedule.

Studebaker is running to capacity. July production totaled 8100 in all models which is as many as the company can build. August will witness the same output. Unfilled orders under present schedules can't be brought down at all.

Buick is going to build 11,750 cars in August, which includes both the new four and the former models. This will be within 250 of the biggest month the company ever had. July production ran between 9000 and 10,000, which is big business.

Hudson-Essex in July ran at about 60 per cent of its 1920 business. This same rate in August will mean 75 per cent of its 1920 business. "Sales are holding up beautifully," is the factory statement and while conditions are admittedly peculiar the companies are confident of plenty of business ahead.

### Cadillac Running Well

Cadillac business is running at the rate of 80 to 100 cars a day. Production in July was slowed somewhat owing to moving operations which are now completed with all equipment installed. The company will devote all of its labor in August to car production. The sales outlook is considered especially bright.

Maxwell and Chalmers produced 1085 and 257 respectively, in July. With Maxwell this represented an increase from 878 in June. Chalmers showed a falling off. Production in August will be based upon business conditions and will adhere to approximately the same schedule shown in July.

Packard business in July showed an increase in twin six sales, ascribed at the factory to the cut in prices. The single six business approximated that of June. Production will continue at the same rate in August. The factory reports little business in trucks.

Oldsmobile business ran at about 70 per cent of normal capacity. Produc-

tion in August will be at about the same rate as in June and July.

Dort reports business in July as running at about 1500 cars. In making comparisons the company, through President Dort, declared business is running in excess of 1919 which it considers a busy year. The company declares business best in big industrial centers.

Hupp in July turned out 1925 cars, or 175 more than in June. The outlook for August is satisfactory and schedules will be continued along present lines. Columbia business in July approximated 60 per cent of normal, keeping up with the June rate.

### Improvement in Briscoe

Briscoe reports a marked improvement in July sales. The plant ran at about 50 per cent of normal. Many dealers and distributors were taken on by the company in July. Liberty business bettered June by 25 per cent. The company's new sport car is making its appearance.

Paige reported July as its biggest month since April, about 1200 cars being produced, which represented a 40 per cent increase over June. The company looks for good business in August.

Saxon business in July ran 20 per cent better than June. The company's new line is making good headway and it reports greatly increased interest on the part of dealers. Wills-Lee is running along at the same rate reached following the introduction of the car to the trade. Sales are steady and good business is looked for in August.

## Larrabee-Deyo Makes New 1-Ton Truck Model

BINGHAMTON, N. Y., Aug 3—A 1-ton, six-speed model is the latest addition to the line of trucks made by the Larrabee-Deyo Motor Truck Co., this city. With this new model, the line now consists of 1½, 2½, 3½, and 5-ton sizes.

This new model is at present being tested out on the road. It has a speed of 55 m.p.h. with 2450 lbs. of dead weight. In a test recently made, the truck was driven from 2 m.p.h. to 30 m.p.h. within 50 ft.

Specifications include the following units: Continental 7-R engine; Brown-Lipe clutch and gearset; Gemmer steering gear; Fedder radiator; and Spicer universal joints in the rear and Thermoid in the front. Other equipment includes metal disk wheels; steel cowl, seat riser and back, with fore doors, all integral.

The wheelbase is 138 in., allowing for 9 ft. of loading space back of the driver's seat. This job complete with electric lights, starter, cab, windshield and express body will list for approximately \$2,000. Tire equipment includes 34 by 5-in. cords.

## North Dakota Sales Dependent on Crops

### Distributors Expect Better Business but Improvement Will Be Slow

NEW YORK, Aug. 3.—With crop conditions fairly well understood, and the crops nearly matured, the automotive distributors of North Dakota are arriving at their estimates of the possible fall business in the sale of cars, trucks, and tractors, and also in the possibilities for business next spring.

North Dakota as an agricultural State is typical of those areas where business in all lines other than agriculture, is reflected almost directly in the condition of crops. As North Dakota did not profit during the war by large crops and war prices business in the State did not get far away from the crop.

Crop conditions in the State are in general a little better than a year ago. In the Southwestern part there is literally no crop, whereas a year ago they had some.

In the Minot area in the Northwest, with the exception of a local zone surrounding the city, crops are 50 per cent over a year ago. In the Devils Lake area in the central north, they are 25 per cent ahead of last year. In Grand Forks, representing the Northeast, they are as good as last year. In Fargo, representing the Southeast, they are about the same as last year. In general motor business throughout North Dakota during this fall and next spring will largely reflect these crop conditions.

### Three Questions Asked

In a canvass made of automotive distributors in the cities of Fargo, Grand Forks, Devils Lake, and Minot, three questions were asked:

1—To what extent do you think the farmer will be a greater buyer of automobiles and tractors in the next twelve months than he has been in the past twelve?

2—How much improvement in the sale of automobiles to the agricultural community are you expecting during the coming fall?

3—Do you think the city and town population will constitute as good a market in the next twelve months as they have in the past twelve?

The replies may be summarized thus:

1.—The farmer's purchases next fall will pretty generally be reflected by his crop condition. In Minot, where crop conditions are good, distributors of low priced cars expect a greatly increased business over last fall. As the scale of prices increases a distributor does not expect a much greater business with far-

(Continued on page 247)

## Many Detroit Plants Planning New Models

### Ford Company Denies Story About New Car—Prices to Change Also

DETROIT, Aug. 2—Many of the factories in the Detroit district are planning new models for appearance in the late summer and early fall months, but the Ford Motor Co. will not be one of them. A statement by the Ford company to-day says:

"Our attention has been called to recent newspaper articles to the effect that there is to be a new model Ford car on the market Aug. 15 with change in design such as a ventilating windshield and one-man top. As we do not contemplate any such changes and there is no foundation to the rumors circulating in this connection, we have no hesitancy in making a denial of the report."

Columbia Motor Car Co. will present its 1922 models on Aug. 15. The new line will embody many new features and is designed to meet the demand for cars along sport lines. New prices will be announced in connection with the new line.

Liberty Motor Car Co. is bringing out a new sport model which will soon be ready for delivery. Prices will be announced when general delivery starts.

Maxwell will meet the demand for cars of greater wheelbase and generally improved appearance by changing its line to a larger vehicle. Necessary changes in equipment are now being made at the factory and by early fall the company will be in production on the new models solely.

## Atlanta Bank Predicts Good Business Future

(Continued from page 236)

mobile sales in this city and in the state at large are considerably less than they were in June. About 400 sales are shown in the city of Atlanta alone, this including trucks, passenger cars, used cars and used trucks, the total for the preceding month being much larger than this. Outside of Atlanta, and especially in the smaller towns, sales during July are also considerably less than June.

Tire sales in this section improved materially during July, in most cases sales for the month being reported in excess of the totals for July, 1920. The increase evidences an early return to pre-war conditions in the tire business. Most of the sales have been in the rural districts, especially in the peach, berry and melon belts, where the farmers and growers have experienced one of their most successful seasons in years. If the business continues as good the remainder of the season as it has the past two months the tire industry in this section, at least, will be on as firm a basis as at any time prior to the war.

### WILLYS FULFILLS PROMISE, 10% OF BANK CLAIMS PAID AUG. 1

NEW YORK, Aug. 3—Fulfilling the promise made a short time ago by John N. Willys that a part of the cash surplus of the Willys-Overland Co. would be used on Aug. 1 to make a substantial reduction in the corporation's bank indebtedness, 10 per cent of the bank claims were paid on that date. The obligations of the company to bankers approximate \$20,000,000. The payment, therefore, was about \$2,000,000. This will leave a substantial amount of cash on hand.

## Harper Bean Balances Show \$600,000 Losses

LONDON, July 22 (By Mail)—The report and balance-sheet of Harper Bean, Inc., covering a period from its inception in November, 1919, to December, 1920, shows a loss for the period amounting to nearly \$600,000, and this does not cover the depreciation which has taken place in the company's investments, which appear in the balance-sheet at cost.

The directors report that proposals will be submitted in due course to reduce the capital of the company by over \$10,000,000. The issued capital is \$30,000,000, but unpaid calls due from shareholders amount to over \$5,500,000 and the directors say it is impossible to collect the bulk of it.

Harper Bean was registered on Nov. 7, 1919, to acquire all the shares in A. Harper Sons & Bean, Ltd., approximately 75 per cent of the shares in the Vulcan Motor & Engineering Co., Ltd., 51 per cent each of the ordinary shares in Swift of Coventry, Ltd., and the British Motor Trading Corporation, Ltd., and, with one exception, all the share capital of six other undertakings, and has since acquired 100,000 ordinary shares in the Birmingham Aluminum Casting Co., Ltd., at \$15, and 196,898 shares in A. B. C. Motors, Ltd.

Conroy, late of Willys-Overland, U. S. A., who became production organizer to the company, has recently started in London as a consulting engineer.

## BIG ORDER FROM FORD

SPRINGFIELD, OHIO, Aug. 3—Ford Motor Co. has placed an order with the Victor Rubber Co. for 200,000 rubber mats for delivery during the remainder of the year. According to announcement made to-night by President H. S. Berlin of the Victor Rubber Co., formerly of Akron, this order is in addition to one for 250,000 mats received from the Ford company early in the year.

The company turned out 900 cord tires yesterday, the largest output of cord tires in its history.

## 500,000 Spark Plugs Sold to Italy in Year

### Gasoline Selling for 80 Cents—Heavy Automotive Taxes Burdensome

WASHINGTON, Aug. 3—The estimated consumption of spark plugs in Italy for 1920 is 500,000 to 600,000, according to a report received from American Consul North Winship, Milan. Of the spark plugs sold in that market, about 90 per cent are of European manufacture and 10 per cent of American make. The importation of German makes has increased and is now estimated to be 60 per cent of the total market. Lire 3 to lire 6.50 is paid by jobbers for plugs, which are resold to dealers from lire 4.50 to lire 7.50.

According to figures published by the government tax bureau for 1920, there were in operation in Italy 25,000 private automobiles, 3,000 public passenger cars, 25,000 trucks and 15,000 motorcycles. These figures are exclusive of army trucks and those used by other government and municipal departments. The number of airplanes in use is about 500, all of European manufacture.

Owing to heavy taxes imposed by the Italian government on the operation of motor vehicles, high-powered and pleasure cars are being stored by a great many owners. Where the use of automobiles or trucks is essential, their number is reduced to the minimum. The sale of spark plugs consequently is diminished.

Spark plugs are classified for import as scientific instruments of precision and the customs duty is lire 125 (gold) per quintal (220 pounds). The rate of exchange on gold is fixed by the ministry of the Italian treasury.

## Prospects for Future Sales Appear Bright

(Continued from page 236)

come into the market, however, there will be additional liquidation of loans by farmers which will tend to make money more plentiful throughout the country.

General buying power in farming communities will depend largely upon the attitude of the bankers. Countless farmers would require the entire proceeds of their crops to meet their bank obligations and if the loans are called relentlessly they will have little left with which to make purchases.

Altogether, so far as the automotive industry is concerned, sales have been far better than any one dared hope in January, and there is every indication that they will go up again with the end of summer. It should not be forgotten that passenger car production for the second quarter this year was 87 per cent of the same period in 1920, which was one of the largest quarters.

## Rolls Royce Reduces Chassis Price \$1250

**Cost Cuts in Production and  
Labor Responsible—Other  
Makes May Follow**

LONDON, July 22 (By Mail)—The Rolls Royce Co. has reduced the sales price of its chassis by \$1250 (normal exchange rate). The reason ascribed is reduced cost of production for labor and materials. The price now is \$9,250. It is believed that this marks the end of the \$10,000 chassis and that Lanchester, Napier and others will follow suit.

Opinion is fairly uniform that prices will have to fall below the new standards set by Rolls Royce before the demand for cars of this type returns with sufficient force to permit the full output of plants to be absorbed. With general industrial conditions settling down, however, it is believed manufacturers of these high grade cars will be able to work off some of the heavy stocks accumulated during the past nine months.

Several other price reductions have been announced in the past month. Charon-Laycock has reduced from \$3125 to \$2875; G. W. K. from \$1750 to \$1550; Hampton from \$2300 to \$2000; Sunbeam from \$4650 to \$4000; Warren-Lambert from \$1925 to \$1750; Waverley from \$2625 to \$2500; Anglo-American Ford from \$900 to \$825; Overland-Crossley from \$1975 to \$1925.

## All H. C. S. Prices Cut; Output to Be Reduced

INDIANAPOLIS, Aug. 1—Effective to-day, prices on all models made by the H. C. S. Motor Car Co. are reduced \$200 in price. The roadster and 4-passenger touring car are cut from \$2,975 to \$2,775, the coupe from \$3,650 to \$3,450 and the sedan from \$3,850 to \$3,650. Prices are f.o.b. factory. Prices were guaranteed until Aug. 1.

Coupled with the price reduction comes the statement that instead of producing nine or ten cars a day as at present, the plant output will be cut to five cars a day, which is the normal capacity.

Officers of the company say that under no circumstances will production be increased. They declare that the working force has been organized to make five cars a day and that nothing will be permitted to disarrange this program.

### HANSON MAKES FINAL CUTS

ATLANTA, Aug. 3—The Hanson Motor Company announces final 1921 price reductions on all its models, effective at once. Prices are f.o.b. Atlanta. Total reductions since Jan. 1 average \$600. The latest cut brings the roadster and five-passenger touring car from \$2,185 to \$1,795; the five-passenger sport model and the seven-passenger touring car from \$2,285 to \$1,895; the sedan from \$3,165 to \$2,885 and the coupe to \$2,775.

### WEED CHAIN PATENT EXPIRES SOON, COMPANY HASN'T "BEEN ASLEEP"

NEW YORK, Aug. 3.—Representatives of the American Chain Co. declined to-day to state what policy would be pursued in reference to the Weed chain when the basic patent covering it, No. 768,495, runs out Aug. 23 next. The only comment made was that "we have not been asleep in reference to the Weed patent." The inference was that the company has prepared to put an improved tire chain on the market. It was said an announcement covering the subject would be made about Sept. 1.

When the patent expires there will be nothing to prevent the manufacture of the Weed chain by anyone who cares to produce it. Infringements will be prosecuted up to the end of this month, however.

The Parsons patent, No. 723,299, under which tire chains were manufactured by the American Chain Co., expired on March 24, 1920.

## Harley-Davidson Cuts Motorcycle Prices

NEW YORK, Aug. 1.—Harley-Davidson Motor Co. has announced price cuts ranging from \$105 to \$130 on all models. The cut took effect August 1. The price changes on the various models are as follows: 74 cu. in. electric twin reduced from \$520 to \$390; 74 cu. in. magneto twin, from \$485 to \$360; 61 cu. in. electric twin, \$485 to \$365; 61 cu. in. magneto twin, \$450 to \$335; sport electric twin, \$445 to \$340; sport magneto twin, \$415 to \$310.

Reductions have also been made in side-car prices ranging from \$40 to \$50.

Other price reductions are looked for in the near future. It has been announced that the Hendee manufacturing company will make reductions on Sept. 1, but the extent of the cut has not been determined. Prices of the Cleveland motorcycle have been cut twice within recent months, while the makers of the Henderson and Excelsior machines made some reductions a few weeks ago.

### NEW PRICES FOR REO

DETROIT, Aug. 1—New prices have gone into effect on the Reo touring car and roadster. The new prices for the touring car and roadster are \$1,650 as compared with \$1,850. Series B coupe for \$2,700.

### CYCLONE TRUCKS REDUCED

GREENVILLE, S. C., Aug. 3—The Cyclone Starter & Truck Co. has reduced the price of its Cyclone truck from \$2,800 to \$2,685. This price includes steel cab top with curtains, windshield, starting and lighting equipment.

## England Hears U.S. May Produce There

**Rumor Also Has It Americans  
Likely to Take Over Existing  
Factories**

LONDON, July 20 (By Mail)—One of the topics which is being discussed by the British automobile trade concerned with the overseas market, is the curious and vexatious irregularities arising out of recent revisions of the preferential tariff in British dominions.

The Indian import rate has been raised to 20 per cent from 7½ per cent, the New Zealand preferential rate is now 10 per cent whereas in Australia it has been reduced to 5 per cent, in South Africa it is only 3 per cent and in Canada it is 7½ per cent. British critics are pointing out that a preferential rate of 5 per cent is insufficient to tempt British makers having regard to the cost of freight, etc.

It may be added that there are continual rumors that American factories will be opened here, or, at least, the taking over of existing ones by American interests for meeting the tariff and other restraints for which a section of the British trade and fiscal reform party are clamoring. It is too soon to deal with the matter, but there is support for certain rumors in well informed trade quarters.

## Palmer Defends Self in Bosch Plant Auction

(Continued from page 237)

In denying favoritism to Kern, it is asserted by Palmer that he did not appoint Arthur T. Murray managing director of the American Bosch but that Murray was elected upon recommendation of Palmer as alien property custodian. Palmer also denies the appointment of directors or any attempt to discourage competition for the purchase of the assets or that he sought to have them sold to Kern.

Palmer denies that Kern caused the company to issue \$1,800,000 in 7 per cent promissory notes and then sold the notes, retaining the proceeds for himself. He also denies that Kern pretended to bring about a dissolution of the company, saying that Kern lawfully brought about its dissolution Jan. 22, 1919, a few days after the American Bosch Magneto Co. was incorporated at Albany.

### SEIBERLING AT REPUBLIC

YOUNGSTOWN, Aug. 4.—F. A. Seiberling, former president of the Good-year Tire & Rubber Co., has inspected the properties of the Republic Rubber Corp. in Youngstown and Canton, now operating under a receiver. Seiberling may purchase the Republic business and plants and merge them with the New-castle Tire & Rubber Co., which he has acquired.

## Will Wage Hot Fight on Federal License

### A. A. A. Summons Owners to Battle Against Additional Impost

WASHINGTON, D. C., Aug. 2—Appeal has been made by the American Automobile Association to 10,000,000 owners of motor vehicles to oppose the proposal of Secretary of Treasury Mellon for a \$10 flat tax on automobiles irrespective of power or size. Statistics have been sent broadcast showing that automobilists are already carrying more than their share of tax burden and that further advances in rates would be obviously discriminatory and iniquitous.

It is said that Chairman Fordney of the House Committee on Ways and Means is opposed to the Mellon proposal for a tax on automobiles because he believes cars of small power should not pay the same rate as larger cars and heavy trucks. The recommendations of the Treasury Department have precipitated a bitter fight in Congress which is not confined to party lines. It is expected that representatives of agricultural districts where there are large numbers of motor vehicles in use will fight the enactment of a motor tax.

Because it is primarily a tax which hits the user of automobiles, the American Automobile Assn. is handling the movement against the Mellon measure but has the support of the National Automobile Chamber of Commerce and other large business organizations. Every automobile club in the country has been asked to bring pressure to bear on congressional leaders and with 10,000,000 automobile owners protesting, Congress is expected to give due thought to the possible economic and political effects of an automobile tax. Attention of House committee on Ways and Means has been called to the fact that car owners are paying a multitude of taxes on their cars including registration fee, driver's license fee, personal property tax, municipal franchise tax, motor fuel tax and other local assessments.

The excise taxes on automobiles will probably be maintained.

### Introduce Bill Asking for Special Motor Tax

(Continued from page 237)

is qualified to operate a motor vehicle upon a public highway.

Section 2 of the Appleby bill would authorize the reciprocity of licenses between all States. A measure of a similar nature is now pending before the Congress and is known as the Pittman-Sweet bill. The Federal registration tax would be affixed and would form a part of the State license tax, which tax could be recognized by the authorities of the several States, as permitting the owner of the automobile to whom the license was issued, to operate the machine within

the confines of any State he may be visiting, or through which he may be passing, without any additional registration or the securing of any other license or tax, or the payment of any additional tax.

### Make New Plea for Sales Tax

WASHINGTON, Aug. 2—Another strong plea was made for the sales tax by representatives of the automobile industry, in conference with Secretary of Commerce Hoover and Secretary of the Treasury Mellon, here. These administrative leaders were unable to hold out any hope for the adoption of the sales tax program because the Administration has advised Congress that a sales tax would not be recommended unless an additional assessment was needed for a soldiers' bonus. Secretary Hoover refused to commit himself and Secretary Mellon indicated that he could not run counter to his present program of tax revision.

The House Committee on Ways and Means has ruled out all testimony regarding the sales tax because it considered it a waste of time to continue hearings, inasmuch as they have already determined that the sales tax would not be incorporated in a new revenue bill.

C. C. Hanch, Chairman of the Tax Committee of the N. A. C. C. told Secretary Hoover that over-taxation and under taxation has been disturbing business equilibrium. He declared that the excise tax was a war measure and should be repealed in all fairness to the automobile industry. It was his contention that this tax is a "stigma" tax upon the automobile and other industries and forms a sales resistance which unbalances normal consumption.

### Hare's Motors Will Go On as Selling Agents

NEW YORK, Aug. 2—Notwithstanding the impending reorganization of the Mercer Motors Co. and the cancellation by Hare's Motors of its contract with that corporation, Hare's Motors will not be dissolved but will continue to function as at present. It will continue as the selling agency for the Kelly-Springfield Truck Co. and probably for the Locomobile Co.

The arrangement with Locomobile will depend upon the decision of the creditors with regard to an extension of their claims pending a possible reorganization, but it is considered practically certain such an agreement will be reached. The extension granted by Locomobile creditors expired July 31 but between 85% and 90% of the creditors already have agreed to a further extension which will run for at least six months.

There will be no change in the personnel of Hare's Motors and even if it is found necessary to liquidate Locomobile it is expected that other lines will be added as opportunity offers.

Stockholders of Mercer Motors will meet Aug. 11 to pass upon the reorganization plan and its ratification is regarded as certain.

## July Sales in Oregon Well Up with 1920

### Many Deferred Deliveries Cause Poor Showing in Figures for June

PORTLAND, ORE., Aug. 1—While registration figures on the sales of new cars throughout Oregon indicated that the month had been scarcely one-third normal, the month of July in Oregon, according to indications, will be unusually heavy in sales of new cars, and when registration figures are known within a few days it is expected they will show the month this year well up with sales of July 1920.

The reason for the poor showing in June was that dozens of buyers of cars during the last portion of that month asked that delivery be deferred until after July 1, thus putting off registration until after that time. This was done because, according to the Oregon registration laws, all licenses taken out during the first six months of the year must be paid for on the full yearly basis, while after July 1 one-half year licenses are required. Thus by deferring taking delivery on cars which they had purchased until after the first of the month purchasers were able to have their license fees cut in half.

Total registrations for June this year in Oregon were 2115 automotive vehicles, according to the report of the Secretary of State's office, of which number 889 were new passenger cars and trucks. During the first week of July registrations were 4200 cars, approximately half of which were new automobiles and trucks. Thus during the first week of July twice as many cars were licensed as during the entire month of June.

### Milwaukee Makers All Operating at Capacity

MILWAUKEE, WIS., Aug. 2—So much progress has been made by distributors and dealers in virtually all sections of the United States during June and July in the merchandising of passenger cars that manufacturers in this district are operating on the heaviest production schedules in effect since March 1. The same is true of manufacturers of motors, frames, transmissions, axles and other parts, which forms an important part of the industry of Milwaukee and southeastern Wisconsin. While substantial increases in output were effected during June, it was not until July 1 that operations assumed a more nearly normal stage and during the month just closed increases in output were made steadily and regularly, demands of distributors and dealers being more regular. At the close of July the Milwaukee plant, or four-cylinder car division of Nash Motors Co., was putting out 50 cars a day, which is capacity in the present works, employing 1000 men on a straight 8-hour schedule.

## June Sales Statistics Show 15.19% Decline from May in Business of 300 Motor and Accessory Manufacturers

NEW YORK, Aug. 1.—Sales statistics compiled by the Motor and Accessory Manufacturers Association from its members, who include the leaders in this branch of the automotive industry, show that there was a decline of 15.19 per cent in June as compared with May. This is the first month of the year to show a falling off in sales, as compared with the preceding month, although the increase for May was very small.

The total of past due accounts showed a small increase in June as compared with May. It was the first month of the year when they were not whittled down. It was encouraging to note, however, that there was a further material reduction in the total of notes outstanding.

The figures for the first six months, compiled from the reports of 300 members of the M. A. M. A., follow:

Month	Total Purchases	Per Cent Change	Total Past Due	Per Cent Change	Total Notes Outstanding	Per Cent Change
January	\$6,264,587		\$8,099,727		\$4,359,871	
February	10,408,962	66.15 Inc.	6,717,165	17.07 Dec.	6,063,118	39.08 Inc.
March	20,120,386	93.80 Inc.	5,608,992	16.57 Dec.	5,069,877	16.38 Dec.
April	26,746,580	32.93 Inc.	5,352,271	4.49 Dec.	5,371,086	5.94 Inc.
May	26,781,350	00.13 Inc.	4,505,176	15.64 Dec.	4,460,355	16.77 Dec.
June	22,703,414	15.19 Dec.	4,720,973	4.79 Inc.	4,012,670	10.37 Dec.

## Peak of Unemployment Reached in Kansas City

FORT WAYNE, IND., Aug. 2.—The unemployment peak, it is believed, has now been reached and with the approach of fall there will no doubt be a distinct improvement in local conditions. A survey of twenty-one employers of the city shows that during the month of July about 10,000 men were totally out of work for the entire month in this city, or worked only a few days. This is the greatest number that has been out of employment in this city during any one month yet.

Some of the city's largest industries are doing little. The General Electric Co., for instance, which at the height of its greatest activity employed 7300, now has about 3000 on its payroll and they are not working full time. These 3000 have just been informed of a wage cut of ten per cent immediately effective, this cut being the second ten per cent reduction of the year.

It is interesting to know that the local gasoline auto pump companies are standing up the best of any of the local industries. S. F. Bowser & Co. have been working 100 men at nights for some time. The Wayne Oil Tank and Pump Co. is quite busy, as is the Tokheim Pump Co.

## North Dakota Field Expected to Improve

(Continued from page 243)

mers. Business last fall with farmers was practically nil, a fact which should be kept in mind.

One tractor distributor in Devils Lake hopes to sell twice as many tractors as last year, and that the automotive sales of the territory will be greater this fall. Even in the Fargo area where crop conditions are about the same as a year ago, more country sales are expected this fall than last by distributors handling medium priced cars.

2.—There is general agreement that business for the next twelve months will show an improvement over the last twelve. The farmer will be a better buyer. He will be in better humor. He

will have liquidated many obligations and while he may not have much ready money he will be more favorably disposed. His credit will be better. Automotive apparatus has been wearing out during the past twelve months and in agricultural areas of sparse population the motor car is such a necessity that the farmer cannot do without it. There is no such thing as a luxury automobile in such a State.

3.—The purchasing capacity of towns and cities in North Dakota is not so definitely agreed upon by distributors in different cities. Minot distributors believe that city buying in the next twelve months will reflect crop conditions, and that buying will be heavier. In cities like Fargo the general feeling is that city buying will be in proportion to crop conditions. The same view is held by Grand Forks distributors.

## Wainwright Arranges 11-Hour Force at Night

CONNERSVILLE, IND., Aug. 2.—The Wainwright Engineering Corporation is starting a night force this week on an eleven-hour shift to supplement the nine-hour day force. This means that business is increasing, as has been the case since the first of the year. The trade in over-sized pistons has surpassed the most optimistic hopes.

So far the Lexington business to date for 1921 is only 12 per cent below 1920, and 1920 was 116 per cent above 1919, according to President F. B. Ansted's statement to department heads. Since the July 1 cut in price the orders for cars are coming at the rate of 250 per week, which is fairly normal, as compared with July, 1920. The price cut has satisfied the sales department.

## TRANSPORT TRUCKS CUT

MOUNT PLEASANT, MICH., Aug. 3.—Price reductions ranging from 11 to 25 per cent on three of the four models comprising its line, are announced by the Transport Truck Company. The 1-ton model is reduced from \$1,850 to \$1,395; 1½-ton from \$2,250 to \$1,995; 3½-ton from \$4,195 to \$3,885. The price of \$2,785 on the 2½-ton is the same.

## METAL MARKETS

AS to the trend of the steel market there appears to be only one opinion. Prices are headed for still lower levels. Considerable divergence prevails, however, in views as to how and when these declines will come about. Majority sentiment inclines to the belief that prices will continue to sag, and that for the immediate present declines of about \$1 per ton may be looked for as a weekly occurrence. In other quarters a more spectacular making over of the situation seems to be anticipated. A Sharon, Pa., correspondent wired early this week that "it is possible that within a week or two steel purchasers will see such a drop in prices as will convince them the bottom has been struck; this, it is said, will turn the industry back to a forward course." Conservative buyers refuse to permit such prognostications, even though they prove correct, to interfere in the least with the program which they have mapped out. They recognize that a period of declining prices is ahead, interrupted periodically by brief reactions. Their aim is to cover their wants as much as possible in the periods of declines and to avoid the necessity of figuring as buyers in periods of short-lived upward spurts of the market. They know that the buyer who would stay out of the market until the last \$1 a ton decline has been registered is usually obliged to place orders in a rising market. It is only natural that steel producers strive to bring about as early a date as possible a return to stability.

Pig Iron.—More inquiries for deliveries over the third and fourth quarters are in the market. Up to the middle of July only small tonnages for immediate shipment were sought, but now a decided upward swing in buying activity has set in. Prices are relatively firm.

Steel.—Full-finished automobile sheets, 22-gage, at around 4.70c. base, are somewhat more firm than the general run of the sheet market, and this in spite of the fact that the demand is rather easier. High-grade blue annealed sheets for crank cases which sold at 2.50c. base, reflect a somewhat lower figure than the 2.25c. quotation for No. 10, now "publicly" quoted. More inquiries are noted for strip steel, the cold-rolled being quoted at 4.25c., although the leading manufacturer of low-priced passenger cars is said to have bought 800 tons at considerably below this figure. Although producers of cold-finished steel bars contend that on the basis of a conversion charge of \$15 a ton they can not shade the 2.50c. base price (hot-rolled bars have now settled down to 1.75c. base), automotive consumers appear to be still offish. Inquiries for bolts and nuts continue to come out and some warehouse stock has passed into automotive consumption.

Aluminum.—The market continues in abeyance. Importers are contesting every inch of the market and some very low offers are reported.

Copper.—The market for the red metal has turned intensely weak and offers of spot metal at as low as 12c. have been turned down.

Tin.—The visible world's supply is placed at 65,000 tons with a continuance of 2000 tons more production than consumption every month. Hence the failure of consumers to respond to prevailing low prices is easily explained.

Lead.—Storage battery demand is slightly better, but the market generally continues easy to weak.

**BANK CREDITS**

*Written exclusively for AUTOMOTIVE INDUSTRIES by the Guaranty Trust Co., second largest bank in America.*

As a result of an increase during the week of \$22,000,000 in gold and \$3,000,000 in other cash reserves, the total reserves of the Federal Reserve System on July 27 stood at \$2,685,000,000. Total deposits increased during the week by \$2,000,000, due to an increase of \$8,000,000 in the member bank reserve account, and a decrease of \$6,000,000 in Government and other deposits, total deposits standing on July 27 at \$1,695,000,000. On the other hand, note circulation decreased by \$27,000,000 to \$2,537,000,000. By reason of these changes the ratio of reserves to deposit and note liabilities combined, increased from 62.5 per cent on July 20 to 63.4 on July 27, while the ratio of gold reserves to note circulation after setting aside 35 per cent against deposit liabilities, increased from 80.6 per cent to 82.4 per cent. These ratios compared with 42.2 per cent and 49.2 per cent on July 30, 1920.

Bills discounted, representing the loans of the Federal Reserve System, declined \$36,000,000 during the week, while bills bought declined \$4,000,000; the total of bills on hand July 27 being \$1,670,000,000. Since Nov. 5, 1920, when bills on hand were at their highest point, \$3,127,000,000, a total decline of \$1,457,000,000 has taken place, of which \$553,000,000 represents the decline in commercial bills discounted. These figures suggest the contraction in the demand for credit since last autumn.

The contraction in the demand for credit is further evidenced by a continued lowering of money rates, which affords a sharp contrast in comparison with conditions a year ago when money was over 8 per cent. The tendency toward easier money, which has been noticeable for the past month, took an extreme form on Thursday of last week when call money dropped to 3½ per cent, the range of the week being 3½ per cent to 5 per cent, compared with a range of 5 per cent to 6 per cent in the previous week. Renewal rate at the end of last week was 4½ per cent. This is the lowest since November, 1919. Time money ranged from 5½ per cent to 5¾ per cent for all maturities compared with 6 per cent the previous week, but demand was light and comparatively little business was contracted. Prime bills for 60 and 90 days' maturities sold at from 5¾ per cent to 6 per cent, other names ranging ¼ per cent above the rate for prime bills, which compares with a rate of 6¼ per cent to 6½ per cent in the previous week.

**FINANCIAL NOTES**

Continental Casualty Corp., New York, in a statement of condition of June 30, shows cash in bank and on hand of \$2,049,242.33 and cash in trust from notes and acceptances

paid \$1,039,714.34. Bills receivable amount to \$841,310.75, notes and acceptances in trust, \$4,778,376.34, bills receivable in trust securing special collateral loans, \$2,822,428.81. Accounts receivable are \$431,381.63, investments \$890,925.21 and total resources of \$13,242,690.31. Collateral trust gold notes come to \$4,975,000 and bills payable, including special collateral loans, \$4,020,334.26.

Biggam Trailer Co., Milwaukee, a new corporation has organized with a capital stock of \$250,000 preferred, plus 1,500 shares of common stock without par value, to engage in the manufacture and sale of trailers and trailer trucks.

Ollgar Co. of Milwaukee, manufacturing transmission devices, has increased its authorized capitalization from \$150,000 to \$300,000 of preferred stock and 25,000 shares of common stock at no par value.

B. F. Goodrich Co. has declared a quarterly dividend of 1¾ per cent on preferred stock, payable October 1 to stockholders of record September 21.

Lee Rubber & Tire Corp. has declared the regular quarterly dividend of 50 cents a share, payable September 1 to stock of record August 15.

Chevrolet Motor Co. of Delaware has declared a dividend of \$3 a share, payable August 2 to stock of record July 30.

**Drake, N. A. C. C. Official,  
to Aid in Census Taking**

WASHINGTON, Aug. 1.—J. Walter Drake will represent the N. A. C. C. on a special committee appointed by the National Association of Manufacturers to co-operate with the Bureau of the Census in compiling the 1921 biennial census of manufactures. In addition, the statistics will be given the Bureau for publication monthly as to production.

The committee will confer with Bureau officials about August 13, regarding the simplification of questionnaires which will be sent out to manufacturers employing five or more persons and it is proposed to limit the distribution to establishments whose products have an annual value of \$25,000, and to approximate values below that figure, based on logical figures, which the conference held to be a logical plan in view of the fact that it was shown that 35 per cent of the plants have an annual production of less than \$100,000 each. It also will be the purpose of the census to set forth only essential facts.

**REVERE SAVED BY COURT**

LOGANSPOUT, IND., Aug. 2.—Judge Souder has ruled that the factory of the Revere Motor Car Corp. should not be sold by the receiver and that the plant shall continue to be operated under receivership of the Citizens Loan and Trust Company of Logansport. The receiver will continue to meet orders for cars. Since being placed in the hands of a receiver several months ago an average of one car a week has been completed at the plant.

**DRUMPELMANN WITH SAXON**

W. L. Drumpelmann, recently resigned as assistant sales manager of Hudson-Essex, has been elected vice-president and director of sales of the Saxon Motor Car Corp., succeeding C. H. Page.

**Transfer of Samson  
Truck Almost Ended****Removal of Plant from Flint,  
Mich., to Janesville About  
Completed**

JANESVILLE, WIS., Aug. 2.—The transfer of the Samson motor truck assembly plant from Flint, Mich., to the headquarters and main works of the Samson Tractor Co. at Janesville, Wis., has been going on throughout the month of July and is now about completed. From 20 to 25 carloads of truck parts, chassis, axles, etc., were received from Flint each week. The motor truck operation will be concentrated at Janesville, although the manufacture of certain parts will be continued at Flint. The Samson works at Janesville already form one of the largest units of the General Motors group and a five-year building program which is now about 40 per cent completed will make it probably the largest plant in the world devoted entirely to the production of agricultural equipment, which includes Samson tractors, Samson farm trucks, Samson nine-passenger farm cars, Janesville tractor implements, etc. J. A. Craig is president and general manager of the Samson Tractor Co., with headquarters at Janesville.

**Oshkosh Tractor Buys  
La Crosse Interests**

LA CROSSE, WIS., Aug. 1.—The Oshkosh Tractor Co. has purchased the entire assets of the La Crosse Tractor Co., which, for the past five years, has manufactured the Happy Farmer tractor, later known as the La Crosse tractor. All the machinery, tools and material will be removed to Oshkosh as soon as an adequate factory can be completed and production of the same models will be continued there. Work on the factory will be started at once.

The plans call for a main building 150 x 500 feet, modernly equipped. The Oshkosh Tractor Co. is capitalized at \$1,500,000 and is headed by A. D. Paine as president and general manager. Paine also is manager of the Wisconsin Tractor Sales Co. I. G. Hickman of Milwaukee is vice-president and C. C. Shanor is secretary, treasurer and sales manager. L. W. Melcher, factory manager and designer of the La Crosse tractors, will act in the same capacity for the Oshkosh company.

**DYER BILL FAILS TO PASS**

WASHINGTON, Aug. 3.—Efforts to pass Senate bill 1060, which is an amendment to "an act to punish the transportation of stolen motor vehicles in interstate or foreign commerce," failed in the House this week and the measure was restored to its place on the regular House calendar. It is known as the Dyer bill and provides a penalty of five years or a fine of \$5,000.

## MEN OF THE INDUSTRY

**R. S. Abbott**, for the past ten years manager of the Atlanta district for the Ford Motor Co. and in charge of the large assembling plant there, has been promoted to the management of the district with headquarters at Houston, Texas. This district includes a large part of Texas and all of Mexico. Abbott is succeeded by W. W. Mitchell, for the past two years assistant manager of the assembling plant at Oklahoma City.

**Ferris R. Miller**, formerly of the publicity department of the Goodyear Tire & Rubber Co., who was transferred to California last year as publicity manager for the new Los Angeles Goodyear Co., has resigned to become commissioner in charge of the Los Angeles Better Business Commission, established to stop misrepresentation in advertising and questionable business methods among merchants.

**Jos. C. de Varona** has been appointed special representative for the Maxwell Motor Corp. De Varona has been with the General Motors Co. for the past five years. He had charge of the Modern Housing Corp. at Flint, Mich., when the General Motors subsidiary erected one thousand houses for its employees. More recently he was sales manager of the Buick branch at El Paso, Texas.

**Roy Davey**, who has been manager of the Detroit branch for the American Bosch Magneto Corp., has been given larger responsibilities at the main office in Springfield, Mass., as acting manager of the manufacturers' trade department. Davey was formerly advertising manager of the Chalmers and sales manager for Bethlehem Motors.

**Sterling H. Keene**, service manager of the National Car & Vehicle Corp., has been granted a leave of absence to enter the U. S. Public Health Service Hospital No. 60, at Oteen, N. C., so that he may completely recover from the effects of being gassed during military service in France.

**C. H. Landsittel** has become sales engineer of the Climax Motor Devices at Chagrin Falls, Ohio, a suburb of Cleveland. He formerly served as director of purchases for the Templar for three years, and prior to that in the same capacity for the Haynes at Kokomo.

**Paul Jones** will direct the new correspondence supervision department of the Franklin Automobile Co. Jones goes to the Franklin company from General Motors in New York, with whom he has held a similar position.

**Alfred Reeves**, general manager of the National Automobile Chamber of Commerce, is spending his vacation at Cape May, while **J. S. Marvin**, assistant general manager, is spending three weeks at Manchester, Vt.

**Klare F. Covert** has been appointed as sales manager in charge of the general sales offices of the Harrison Radiator Corp. of Lockport, N. Y. Covert succeeds H. R. Lewis, who resigned.

## INDUSTRIAL NOTES

**National Gauge & Equipment Co.**, of La Crosse, Wis., manufacturing gasoline and oil measuring gauges, pressure indicators, meters and similar motor car equipment, is now operating at from 75 to 80 per cent of capacity, a substantial gain over July 1, when it has reached 60 per cent of capacity. Current orders are of a volume insuring capacity operations by early fall.

**Emerson-Brantingham**, Rockford, Ill., farm implement and tractor manufacturers, have closed for inventory, but Charles S. Brantingham, president, said the reopening in September will not be determined until trade conditions become clarified. The plant has been operating with about 50 per cent force on 60 per cent time.

**Clark-Turner Piston Co.** of Los Angeles, has completed a modern factory building containing approximately 50,000 square feet of floor space. Production of De Luxe pistons has been greatly increased and the business has been developed not only in the United States but in many foreign countries.

**Temme Spring Corp.** recently signed a contract with American Autoparts Co., Detroit, under which the entire output of replacement springs of the Detroit plant will be handled by the Temme Company.

**Fisher Body Co.**, Cleveland, is completing its local plants and machinery has been installed. Production has not started, but the completion of drawings and die plant can be placed in operation within 60 days.

**H. H. Franklin Mfg. Co.**, Syracuse, will operate five days a week during the balance of the summer, instead of five and a half days as at present. Production will be maintained at around 40 cars a day.

**Rolls Royce Co. of America** has closed its plant in East Springfield, Mass., for five weeks. Approximately 800 employees have been at work in the factory, which has been operating on a full-time schedule.

**Jefferson Rubber Co.**, Jefferson, Wis., has purchased approximately \$50,000 worth of new machinery for immediate installation to bring the capacity to the point required by current orders.

**Ford Motor Co.** has begun the erection of a new steel building for the welding department of its Northville, Mich., factory. The output there is averaging 57,000 valves and valve stems daily.

**Greenfield Tap and Dye Corp.** which closed its plant for July is beginning to open up departments and is employing more than 300 hands.

**Franklin Automobile Co.**, retail orders for July to date exceed those received during similar periods of either April, May or June.

**Hartford Scripps-Booth Co.**, has filed a certificate of dissolution.

Reo Returns to Old Home  
Under J. Frank Witwer

**KANSAS CITY, Aug. 3.**—The Reo passenger car and truck wholesale and retail distribution for Kansas City and territory returned Aug. 1 to its original home, The Southwest Motor Company. Reos were sold by this company at 1612 and 1614 Grand Ave. from 1910 to 1919, making the longest continuance representation in one location in Kansas City motor car history.

The company has the same territory for Reos as before, including western Missouri and northern and eastern Kansas. In the interval of two years that Reos have been handled by another company, the Southwest Motor Co. has distributed and retailed Jordan passenger cars. There will be a separate traveling force and sales organization for the Jordan. The company has not handled a truck in the past two years. J. Frank Witwer is president and general manager of the Southwest Motor Co.

Fordney in Favor  
of Graham MeasureResolution Will Be Pushed—  
Dealers Believe Bill Will  
Protect Them

**WASHINGTON, Aug. 3.**—Chairman Fordney of the House Ways and Means committee has indicated that special attention will be given the Graham resolution calling for a levy of 300 per cent on reimported war supplies. It is expected the resolution will be reported out either this week or next, in order that it may be considered in the House before debate begins on internal tax revision. Automobile dealers believe that the Graham resolution will afford better protection against underselling by foreign speculators than the tariff bill pending.

The Graham resolution is more drastic than the provisions carried in the House tariff bill and it levies specific duties which are prohibitory. With the resolution through the House, its passage could be expedited in the Senate and the resolution would become effective several weeks before the tariff bill is enacted, thus putting an immediate check on reimportation activities.

It is known that majority members of the Ways and Means committee are in favor of this proposition as interim legislation. They are receiving numerous complaints to the effect that European and American speculators are selling American war supplies at prices which defy American competition.

Prudden Has Best Day  
Since May a Year Ago

**DETROIT, Aug. 3.**—Production in the Prudden unit of the Metal Wheel Corp. at Lansing on July 26 exceeded any previous 10-hour output. The biggest previous day was in May, 1920. The Prudden and other units of the corporation now are operating 10 hours a day with Saturdays off. The plants will be operated Saturdays this month if shipments are not delayed.

The Michigan Screw Co. at Lansing reports better business in July than was anticipated. Several unexpected orders were received and the output was up to the 50 per cent mark the entire month. Operations are expected to slow up this month but prospects are bright.

## CUT KALAMAZOO TRUCKS

**KALAMAZOO, MICH., Aug. 3.**—Reductions ranging from \$300 to \$425 on all models of its trucks were announced by the Kalamazoo Motors Corp. Two new models also will be added to its line. The model G-1 1½-ton is reduced from \$2,800 to \$2,495; model G-2 1½-ton from \$3,100 to \$2,800; the 2½-ton from \$3,700 to \$3,275; the 3½-ton from \$4,300 to \$4,000; the 5-ton from \$4,800 to \$4,500. A new 3-ton model will sell for \$3,700 and a special road builders 5-ton new model for \$4,800.

# Calendar

## SHOWS

Sept. 5-10—Indianapolis, Automobile and Accessory Show in conjunction with Indiana State Fair, conducted by Indianapolis Automobile Trade Association, John B. Orman, Mgr.

Sept. 28-Oct. 8—New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January—Chicago, Automobile Salon, Hotel Drake.

Jan. 7-13—New York, National Automobile Show, Madison Square Garden, Auspices of N.A.C.C.

Jan. 28-Feb. 2—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.

Sept. 9 to 17—Ottawa, Ont., Can.—Ottawa Motor Show.

Feb. 6 to 11—Winnipeg, Can., Automotive Equipment Show, Western Canadian Automotive Association.

## FOREIGN SHOWS

September—Buenos Aires, Argentina, Passenger Cars and Equipment, La Pabellon de las Rosas, Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery, Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Sept. 5, 1921—Constantinople, Traction trials under the direction of the Turkish Ministry of Agriculture.

Sept. 23-Oct. 2—Berlin, German National Automobile Show, Auspices of German Auto-

mobile Mfg. Ass'n and German Automobile Club.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.

November 7-14—Paris, Seventh International Exposition of Aerial Locomotion in the Grand Palais of the Champs Elysees, Held by the Chambre Syndicale des Industries Aeronautiques.

March, 1922—Santiago, Chili, Annual Automobile Show.

## Milwaukee Firm Plans to Keep All Employed

MILWAUKEE, WIS., Aug. 3—To keep its entire capacity employed to a maximum, the Beaver Mfg. Co. of Milwaukee, a large manufacturer of motors for passenger cars, trucks and tractors, has started a campaign for patronage from garages and private owners for repairs and replacement work. The works cover 100,000 sq. ft. Large newspaper display space is being used to announce the new department, as follows:

"The greatest fear of the passenger or commercial car owner is motor trouble. Too much time and money is lost while repairs are being made. We can save you time and money and insure better performance when you need repair service or parts of any description. Our equipment permits us to take work of any size. Each individual order receives prompt, efficient attention. Over nineteen years of motor building has given us knowledge of materials and workmanship which you can use to advantage.

"We have in stock, for all makes and models of motors: Bearings, either connecting rod or main, of any type; copper asbestos cylinder head gaskets; pistons, piston pins, rings and bushings, either standard, oversize or special; timing and starting gears; valves, etc. We can regrind your cylinders and furnish special light weight pistons. You can get quick, accurate service on any crankshafts to be reground."

As a special offer, the Beaver company makes a price of \$20 for regrinding Ford cylinders, including oversize pistons, complete with rings, pins and bushings.

## Sale of Holton Assets Is Approved by Court

INDIANAPOLIS, Aug. 3—The sale of the Holton Tractor Co. assets was approved by Judge Solon J. Carter in Superior Court, before whom a receivership action by creditors of the company was pending. The tractor com-

pany, while a Delaware corporation, had all its assets in Indianapolis, together with factory equipment, and plans had been made for the manufacture of the tractor on a large scale here. Lack of capital, however, prevented the company from making a success and last December the company was placed in the hands of a receiver.

The tractor company was sold to Elwood Haynes, of Kokomo, president of the Haynes Automobile Co., other Kokomo business men and George J. Marrott of Indianapolis. Mr. Haynes will be president of the new company, Mr. Marrott and A. G. Seiberling, vice-presidents, John Powell, secretary, and Mr. Marrott, Mr. Seiberling, Mr. Powell, Mr. Haynes, J. W. Johnson and Si McQuiston, directors. The new company will be a \$2,000,000 corporation, manufacturing a tractor, another tractor known as the Powell tractor, and other features acquired by the company after months of experimenting. The new product will be known as the Haynes tractor.

The creditors of the Holton company will receive about \$100,000 in 7 per cent cumulative preferred stock in the new corporation, and persons who held common stock in the company will receive part of their holdings in common stock of the new company, common stock aggregating from 25 to 33 per cent being received by these holders of common stock. It is said practically all of the creditors had signed agreements accepting the proposition.

## Jersey Firm Takes Over Chevrolet Branch Plant

CAMDEN, N. J., Aug. 3—The Millwood Motor Car Co. is a new organization which has taken over the distribution and retail sales of Chevrolet cars for the Camden territory. With the change, the factory branch of the Chevrolet Motor Co. here will be discontinued. The Millwood organization takes over the building, stock of parts and organization of the factory branch.

## New Mercury Car Soon to Be Made in Canada

MONTREAL, QUE., Aug. 3—The Canadian Automobile Corporation has started factory operations at Lachine where it has taken over the plant of the Rapid Tool and Machine Co., Limited, pending the erection of a permanent plant in Longueuil parish, a site which was purchased recently. The car to be produced is the Mercury Six.

The actual assembly of parts was started three weeks ago. Those in charge of the factory are G. E. Brennan, and H. Potter, formerly engineer and production expert to Stevens-Duryea. All engineers in charge of the factory, which is expected to give employment to about 150 men, have been connected with motor construction for long periods. The directors of the company are F. W. Stewart, vice-president Cluett, Peabody Co., of Canada, Limited, and an ex-chairman of Montreal section of the Canadian Manufacturers Association, chairman of the board, H. W. Austin, managing director of Perrin Kayser, Ltd., vice-president; J. D. Henderson; D. L. Harrington, president and general manager Rapid Tool and Machine Co., Ltd. M. H. Potter, John MacNaughton, and R. J. M. Cantell, all of Montreal.

The site purchased at Longueuil comprises 163,000 sq. ft., and the company is contemplating erection in the near future. Arrangements have been made with the Grand Trunk for a siding.

## French Air Exposition to Be Held November 12

PARIS, July 20 (By Mail)—The seventh French aeronautical exposition will be held at the Grand Palais in the Champs Elysees Nov. 12-27. No exhibition was held last year. The general classification of exhibits includes aerostats, heavier than air apparatus, engines and propellers, aerial navigation, motor boats, machine tools and raw material, transportation and housing.

## Why Our Motor Fuel Supply Must Be Conserved

Half of our original domestic reserve is already consumed. Over one-fourth of last year's requirements were imported from Mexico. Economy in the use of remaining supplies is of the utmost importance.

By Herbert Chase

**A** WELL-KNOWN quotation might well be paraphrased to read "in time of plenty prepare for drought." As applied to the motor fuel situation this is no jest. The price of gasoline is down almost to pre-war levels. At the moment this may seem to be a good thing for the automotive industry, but there is good reason to question the apparent benefit if the effect of the future is taken into consideration. Low prices brought about by over-production are apt to encourage careless use, and what is more important, discourage attempts to increase economy or to provide substitutes which in this case would add to the total supply of motor fuel available.

In times of drought there are always some drinkables available. So will there always be motor fuel. During the year 1920 nearly 450 million barrels of crude petroleum were produced in this country. If production could continue at this rate it is estimated that domestic reserves would be exhausted in about thirteen years. That does not mean that there will be no gasoline, or its equivalent, available in this country thirteen years hence. Far from it. Some domestic petroleum wells will no doubt still be yielding oil after the close of the present century and thousands of new wells will yield valuable fuel between that time and this.

Let no one rashly conclude that an industry so basically sound as that which supplies automotive transportation for the great nations of the world will disappear simply for lack of petroleum resources upon which to feed. On the other hand, no competent person who has thoroughly and conscientiously studied the facts can deny that all forms of petroleum will become more scarce and consequently much more expensive well within the next decade.

Having read thus far, someone will doubtless remark, "Old stuff. We have heard this talk of a motor fuel scarcity for several years, and there is still plenty of gasoline to be had. Why worry?" To which we reply, "Don't worry, but give heed to the facts—facts which are even more apparent than they were when they first began to attract attention."

Then what are the facts?

We have endeavored to make some of them clear in the accompanying chart, Fig. 1. It will be seen that on January 1 of this year nearly half of the estimated total original supply of crude petroleum of this country, amounting to about 11.4 billion barrels, had been consumed. Of this amount nearly 15 per cent was used during the calendar years 1919 and 1920 alone.

Fig. 1—Chart showing relation between estimated original supply of crude petroleum in U. S., production to date and consumption last year. Compare the white block showing remaining supply with the amount produced last year.

The small block marked "U. S. production of crude in 1920" is drawn to the same scale as the block showing total original reserve. It should be compared with the block representing the unmined supply remaining in January, 1921, which is about thirteen times larger.

If it were possible to maintain last year's rate of production for the next thirteen years our entire supply of crude would be extracted from the earth by the end of that period. It is certain that this will not happen, but it is equally certain that the price of crude will mount and that all petroleum products will also increase in price as the domestic supply approaches exhaustion. This, in turn, will result in strenuous efforts to use all petroleum products to greater advantage. Many such efforts are now being made. It is to be hoped that they will be redoubled.

The second small detached block, marked on the chart "U. S. consumption of crude in 1920," is significant partly because of its size in relation to the block marked "U. S. production in 1920," referred to above.

It is clear that our domestic consumption of petroleum is much in excess of our domestic production, a situation which has now existed for several years. Last year there were consumed in this country 531 million barrels of crude as against a production of 443 million barrels. The difference was made up by imports from Mexico which were more than double the imports of the preceding year. Had there been no Mexican supply or had political conditions interfered with receipt of imports we should already have felt the stringency which is certain to come later. It is evident that a condition in which domestic consumption exceeds domestic supply cannot continue indefinitely without such a stringency unless the widening gap is filled by imports.

It has fortunately happened that large supplies of Mexican crude were available, and that these were relatively close at hand so that the cost delivered at our seaboard was small in comparison, let us say, to the price that would have obtained had we been under the necessity of transporting the oil as far as most

European countries have to carry their imports of oil.

Under these circumstances it is quite apparent why Doctor Pogue, in last week's issue of *AUTOMOTIVE INDUSTRIES*, made the statement that "should the curve of Mexican production turn sharply downward in 1922 or 1923, the effect upon the petroleum situation in the United States will be significant."

This leads us to consider the questions which are inevitably raised when the subject of available supplies of crude petroleum is raised: Who knows the extent of supplies thought to be available, and who can say that there are not great undiscovered supplies which will take the place of supplies now known to be failing? Those who are familiar with the history of oil discovery on this continent are apt to point to the fact that heretofore when failing supplies in some fields have threatened to cause a shortage, the impetus given to wildcatting or search for new fields has always resulted in discoveries of such fields as those in Oklahoma and in Mexico which have forestalled the scarcity predicted. Will not this happen again? These are natural and legitimate questions which demand a reply.

In matters of this kind it is necessary to depend upon the geologist, for intelligent estimates can be made only by a knowledge of petroleum geology and a study of production from pools of known geological character. Figures concerning reserves given in this article are deduced from surveys made by the U. S. Geological Survey. The figures are generally regarded as conservative, but some well-informed persons consider the estimates rather too high than too low. It should not be forgotten that the estimates may prove to be too high rather than too low. They are admittedly only estimates, but they are based upon careful surveys and sound engineering deductions, and consequently are a far better guide than the offhand conclusion that, because we have always succeeded in finding oil when it was needed, we shall always be able to do so.

Oil is known to occur in certain types of geological formations, and conversely, where this type of formation does not exist, there is no reason to expect that oil will be found. The geological character of a given section is determined largely by outcroppings of rock or by the nature of material brought to the

Fig. 2—Chart showing comparative production of petroleum products in U. S. in the last three calendar years. Note the large proportion now used as gas and fuel oil. If this fraction could be used for motor fuel, our potential supply for automotive transportation would be more than doubled

surface in drilling operations. In the great level coastal plains or swamp lands which occur in territory such, for example, as that adjacent to the Gulf of Mexico there is often little to guide the geologist in search of oil. When by so-called wildcat drilling, more or less at random, oil is discovered in territory of this kind, the yield is often very great at first, but decreases rapidly and is soon exhausted, as in the case of some of the Texas and Mexican pools. Geologists anticipate that much oil will yet be discovered along our coastal plains, but the possibility that new fields of the character of those found in Pennsylvania and Oklahoma, for example, will be discovered is, to say the least, extremely doubtful.

For this and other reasons it is conservatively predicted that the curve of petroleum production in

this country will soon reach a peak, if, indeed, it has not already done so, and will thereafter rapidly decline. This, in the face of constantly increasing consumption, is sufficient reason why any industry which is largely dependent upon petroleum products for fuel should sit up and take notice.

So much for the domestic situation. Now as to the possibility of supply from foreign sources. The keen international competition for the control of oil fields wherever they exist is sufficient indication that the great value of petroleum is fully appreciated.

Mexico, next to the United States, has been the second largest producer of petroleum and was not long since producing at about half the rate at which this country was producing. It is estimated that Mexico's proven reserve will have been about half exhausted by the end of this year, and very little, indeed, is being done to locate new supplies there, although in well-informed circles there is expectation that great quantities of oil will still be secured in Mexico. If this possible potential supply is developed in time it will simply postpone the date when a scarcity is felt. It is a doubtful dependency to say the least, especially when it is recollected that the gasoline content of Mexican crude is lower than that of most other crudes.

Fortunately the Mexican supply thus far produced has been close enough at hand to be cheaply transported to this country. Fields yet to be discovered in Mexico may be much less accessible, and the

product consequently much more expensive.

It is quite common to hear the remark that there are ample supplies of petroleum on other continents to meet the world's demand, should the supply in this country and Mexico prove inadequate for our needs. It is said that there is oil in China, in Siberia and in several South American countries. How much, nobody knows. So far as China is concerned, we are told by one prominent engineer who has visited that country in quest of oil lands that the probable supply underground is not promising. Some of the known sources of supply in South America are extremely inaccessible, and even if they were close to the seaboard the cost of transportation to this country would be very great. Much the same applies to Siberia, concerning whose petroleum resources but

little appears to be known.

To sum up the situation, so far as imports are concerned, it may be said that the future supply is, at best, uncertain. Much petroleum will doubtless be imported to supplement our domestic supply, but with the possible exception of imports from Mexico, the cost of importation will be great and the price correspondingly high.

What, then, is to be said of the remarks dropped on occasion by certain persons of standing in the oil industry who blandly state that there are ample reserves of petroleum in this country to meet all demands for several generations to come? Some persons have reached the conclusion that profits made in selling oil securities

are the controlling factor in arriving at this conclusion, rather than a careful weighing of the evidence.

On the whole, it must be said that, while we shall doubtless have an abundant supply of cheap motor fuel for some little time to come, such fuel is certain to become increasingly expensive in the not distant future. This is not a pleasant fact to record, but it is worse than useless to ignore what we know to be true and calmly proceed as if there would always be ample supplies of inexpensive motor fuel.

If we accept this view, and there appears to be no alternative, what is to be done about it? If the industry is willing to think and act far enough in advance of what is now clearly evident, there should be no insurmountable difficulty in adjusting the industry to changed conditions. If, on the other hand, there is a disposition to wait until the forecast stringency is at hand, the

**S**TATEMENTS are current to the effect that the petroleum supply of the United States will be exhausted within a score of years. Such statements are misleading. Decline curves of the older oil-fields indicate that this country will be producing petroleum fifty years hence, perhaps even into the next century, but in greatly diminished volume.

Irrespective of the quantity of recoverable petroleum underground, the output of this country must inevitably decline. This decline, however, may be expected to be a slow recession over a considerable number of years, rather than a sharp and sudden curtailment. The peak of production was possibly reached in June of this year. That this record will be bettered is unlikely, although it can doubtless be surpassed if we are willing to pay the price. But whether the output of petroleum in the United States has actually or almost reached its maximum rate is immaterial. Likewise, the exact size of the unmined reserve is of secondary importance. The point to be emphasized is the coming necessity for increasing the over-all efficiency of petroleum—a problem that concerns not only the producers and refiners of oil but the manufacturers of appliances that consume its products, as well. From now on the tendency will be to use relatively less of the material itself, but to put greater effort into increasing the service value extracted from it.

There is no valid reason why any activity fundamentally dependent upon liquid fuel should meet with permanent restrictions in energy supply. The heat units available in liquid form are practically limitless, so far as present generations are concerned; we properly utilize only a few per cent of those contained in petroleum and almost entirely neglect the content of leaner resources such as oil-coals and oil-shales. Readjustments in our economic practice there must be; restrictions in our economic growth there need not be. A lessened supply of crude petroleum would present an opportunity; not a handicap.

JOSEPH E. POGUE.

industry is certain to feel the effect more severely than it would otherwise.

**There are several courses of action, all of which should receive serious consideration:**

**First**—Every effort should be made to economize in the fuel consumption of cars now in service. There is abundant evidence that these cars use on an average of 20 to 30 per cent more fuel than would be required with properly designed and heated manifolds and properly adjusted carbureters. Manufacturers might, if they would, greatly decrease this waste by providing their service stations with proper instructions and facilities for correcting the faults which result in this waste, and encouraging car owners to avail themselves of these facilities.

**It must be quite evident that the nine million cars now on the road in this country will eat heavily into existing domestic fuel reserves before they are worn out. Much can certainly be done by educating the owner in the need for conserving fuel and assisting him to secure economical operation.**

**Second**—All automotive engines turned out in regular production from now on should be made in such a way as to consume the least possible fuel in the service for which they are intended. Numerous ways in which they can be made more efficient in fuel utilization were summarized in an article entitled "Where Are We Getting in Efforts to Solve the Fuel Problem?" which appeared in the June 16, 1921, issue of AUTOMOTIVE INDUSTRIES, and articles dealing with various phases of this subject are continually being presented in these pages.

**Third**—Intensive research and development work should be undertaken, not only with a view to producing more economical engines, but with the object of developing types of engines which will use economically less volatile fuels than present-day gasoline, preferably those fuels now classed as gas and fuel oil, or a mixture of such oils with gasoline and kerosene. Such engines would preferably adhere as closely as possible to present automotive types, but if a change in type ultimately proves desirable from an economy standpoint, even at the expense of some complication, such a change should be given serious consideration. By reference to Fig. 2, taken from Doctor Pogue's review of the oil industry for 1920 (see AUTOMOTIVE INDUSTRIES for February 17, 1921), it will be seen that over half of our domestic production of crude is consumed as gas and fuel oil.

**If the automotive industry had to-day ready for production engines capable of using gas and fuel oil or a mixture containing all fractions of the crude above those classed as lubricants, the potential supply of motor fuel would be more than doubled. Evidently, then, it is very much worth while to look toward the development of such an engine.**

**Fourth**—Every possible encouragement should be given to the production of gasoline substitutes, even though the promised supply of such fuels as benzol and even alcohol will be very small for many years to come in comparison with the total consumption of motor fuel.

**Fifth**—No stone should be left unturned which will tend to encourage the ultimate production of large quantities of motor fuel from shale oil. It is recognized, of course, that the production of shale oil will never be profitable until crude petroleum advances very considerably in price. There is also great need for investigation to determine what methods of recovering oil, and especially motor fuel, from shale can be used to best advantage. The Bureau of Mines is doing some research in

this direction. Funds should be provided to carry this work forward on a large scale and as expeditiously as possible. Automotive manufacturers should make it their business to see that Congress provides funds for this and other work of similar character (that at the Bureau of Standards, for example) calculated to make available new motor fuel resources or make existing supplies go further. Government bureaus are in an excellent position to undertake work of this kind if allotted sufficient funds, and the great economic importance of the whole matter more than justifies the expense.

It should be understood that the recovery of oil from shale involves extensive mining as well as refining operations which require years for development. One commentator draws attention to the fact that "the development of a shale oil industry on a scale sufficient to furnish large quantities of motor fuel is an undertaking comparable to the creation of the whole coal industry of to-day." It will require much time for development, hence a sound foundation on which to build profitably when the demand comes should be prepared now through research and development work.

**Sixth**—Since increasing quantities of motor fuel are being consumed by commercial vehicles it is important that particular attention be paid to making them as economical of fuel as possible. As the cost of motor fuel increases, the differential in favor of types of vehicles using it, in comparison with other forms of transportation, will decrease. Since the electric vehicle is not in any way dependent upon motor fuel, its future utility may be much increased in comparison with the gasoline-propelled type, and possibilities in this direction should not be overlooked in broad consideration of the fuel problem. Where stops are frequent and fuel is apt to be wasted in engines running idle when the vehicle is not performing useful work, the electric vehicle possesses certain advantages. Generally speaking, the vehicle which is most economical in all-round performance is the one to be advocated for that particular use.

**In conclusion let it be emphasized that the situation is one of grave import to the automotive industry. It is idle to deny this fact and indiscreet, to say the least, not to prepare to face it squarely. The industry should organize its forces in such a way as to accommodate itself with the least possible disturbance and as gradually as the situation permits, but no time should be lost in so doing. Automotive transportation is too firmly fixed in our modern social and industrial system to be displaced or abandoned simply for lack of the same abundant supply of cheap fuel which it has always enjoyed. It is unthinkable that this should occur, but we must certainly prepare for readjustment to meet the coming fuel situation, and should do so without an undue period of speculation as to just when the stringency will actually have to be met.**

**W**ELDING of cast iron is very difficult, inasmuch as a part of the silicon content is lost by evaporation or burning; then the exceptionally hard white specular cast iron is formed that makes it impossible to touch up the welded spot with the file. Furthermore, when the specular iron cools down it easily cracks. These drawbacks are avoided, according to German patent No. 222,690, by using for welding cast iron bars very rich in silicon and carbon, preferably bars of pure hematite, pig iron or charcoal iron. Owing to the high carbon content of the bars "burning off" is prevented. The welding should be performed as rapidly as possible and with a powerful flame, then cooling slowly in hot ashes.

# New Buick Four Similar to Six of Same Make

Some innovations are incorporated. New model has separate cylinder head with valves seating directly in the casting. No cages are employed. Single universal is enclosed in ball joint attached to rear of gearbox and is lubricated from this unit. Wheelbase is 109 in. Weight 2380 lbs.

By J. Edward Schipper

**T**HE Buick Motor Co. has added to its line a four-cylinder chassis upon which are mounted bodies of the roadster, touring car, coupe and sedan type. While this additional model is new throughout, it embodies all the characteristics of Buick practice, including a valve-in-head engine. Conservative body designs are a feature of the new line, the bodies being similar to those of the six-cylinder model. A wheelbase of 109 in. is standard for all body sizes and the whole line is equipped with 31 x 4 in. Royal cord tires, a new straight side size made by the United States Tire Co. for this model.

A detail study of the four-cylinder car shows that all the improvements made during the last few years on the six have been incorporated also in the design of this four. From a performance standpoint, the new model should prove adequate in any part of the country, whether it be hilly or flat. With a brake horsepower of 35 to 40 and a shipping weight for the touring car of 2380 lb., the car weight per horsepower is about 60 lb. The final reduction is 4.6 to 1 for all models. This is the same as the ratio used in the five-passenger, six-cylinder car and less than that used in the seven-passenger touring, which is geared at 4.9 to 1. In this connection, however, account must be taken of the fact that the tires on the four-cylinder are only 31 in. in diameter, while those on the five-passenger six are 33 in., and those on the seven-passenger six 34 in.

Cylinder head, cylinder block and upper half of the crankcase are individual iron castings. The lower half of the crankcase is a pressing forming the oil pan, and above the cylinder head is a stamped cover plate which houses the rocker arms and the remainder of the overhead valve mechanism. The four cylinders are cast in a block and have a bore and stroke of  $3\frac{3}{8}$  by  $4\frac{3}{4}$  in. This gives an S. A. E. rating of 18.23 hp. and a displacement of 170 cu. in. The cylinder block is a remarkably simple casting, consisting only of the cylinder barrels

and water jacketing for the upper part of the block. The manifolds are cast in the cylinder head. The valves seat direct in the head casting and operate in pressed-in guides. No cages are employed. The cylinder head casting is cored for water spaces around the spark plugs, valves and manifolds. The piston is cast iron and is of the three-ring type with all three  $\frac{3}{16}$ -in. rings located above the piston pin. Below the bottom ring there is a wiper groove so designed that it will scrape the oil off the wall of the cylinder and lead it to the piston pin bearing. The piston pin bearing is located in the upper end of the connecting rod and the pin is offset  $\frac{3}{32}$  in. toward the camshaft, the

same as in the six-cylinder model. The diameter of the piston pin is  $\frac{3}{4}$  in.

The connecting rod is 12 in. in length, which is exceptional for this size engine. It is a drop-forged I-section rod and carries at its lower end a babbitt-lined bearing 2 in. in diameter by  $1\frac{5}{8}$  in. in length. The crankshaft is of carbon steel, its large diameter rendering it very rigid. The diameters and lengths of the three crankshaft bearings (front to rear) are as follows: 2 by  $2\frac{1}{16}$ ; 2 by  $1\frac{3}{4}$ ; 2 by  $2\frac{23}{32}$  in. The front and intermediate bearings have two bolts each and the rear main bearing has four bolts.

Camshaft drive is by helical gears. The cam followers are of the roller type, the cams acting against push rods which carry a mushroom-shaped spring retainer at the lower end. The tappet guide contains a coiled spring which helps to keep the roller follower in close contact with the cam and acts as an auxiliary to the valve spring. The push rods have a ball and socket connection at the rocker arm or upper end, where the adjusting means are also located. The ball is hardened and ground. The rocker shaft is supported on the cylinder head, the rocker arms being provided with a rocking chair motion on the upper end of the vertical overhead valve stem.

Instead of all valves being interchangeable, the intake valves are larger than the exhaust valves. The

Side view of four cylinder Buick engine, showing pump, generator and ignition unit drive

Sectioned elevations of Buick four-cylinder engine

On left: Buick 3-speed gearset and dry disk clutch. In center: Clutch throw-out lever and clutch pedal adjusting device. On right: Side view of transmission with pedal

Sectional view of rear axle and brake and details of same

clear diameter of the inlet valve is  $1\frac{7}{8}$  in. and that of the exhaust valve  $1\frac{5}{8}$  in. These valves are larger than those of the six-cylinder engine, although the displacement per cylinder is very nearly the same. The valves of the six are  $1\frac{5}{8}$  in. for the inlet and  $1\frac{1}{4}$  in. for the exhaust. On the form the valve lifts are  $21/64$  in. for the inlet and  $5/16$  in. for the exhaust. The stem diameter is the same for both, viz.,  $\frac{3}{8}$  in. The material of the valve head is cast iron and that of the stems carbon steel. A spring pressure of 76 to 85 lb. is employed, the same as on the six-cylinder car. The valve timing is also identical with that of the six, and is as follows:

Inlet opens 22 deg. 10 min. after upper dead center.

Inlet closes 45 deg. 10 min. past lower dead center.

Exhaust opens 53 deg. 50 min. before lower dead center.

Exhaust closes 9 deg. 10 min. after upper dead center.

The firing order is 1-3-4-2. This timing, in conjunction with a 74 lb. per square inch gage compression pressure, indicates that the engine has high-speed characteristics.

Oiling is by the circulating splash system, the gear pump being located in the oil pan and driven directly from the camshaft. The pump is so constructed that it can be taken out from below for cleaning or inspection and is entirely exposed to view when the pan is dropped. The capacity of the oiling system is 4 qt. The crankshaft and main bearings, as well as the timing gears, are supplied directly from the circulating system, while cylinder walls and other internal parts are taken care of by the splash from the scoops on the lower end of the connecting rods.

#### Gasoline System

The gasoline system comprises a 10-gal. cylindrical tank mounted at the rear of the chassis beneath a sheet steel cross-member. From this tank the gasoline is drawn to a vacuum tank on the dash and fed by gravity to the  $1\frac{1}{4}$ -in. Marvel carbureter. The carbureter is a top-outlet type, mounted on a separate intake manifold. The diameter of the intake manifold at the throat is  $1\frac{3}{32}$  in. A damper which controls the exhaust heat utilized is interconnected with the throttle so as to give more heat at low and less heat at high speeds.

The cooling system comprises a square tube cellular radiator having a water capacity of  $3\frac{1}{4}$  gal. and a radiating surface of 304 sq. in. It has a depth of  $2\frac{1}{2}$  in. and is fed by a centrifugal water pump driven off the generator shaft. Cooling is assisted by a 16-in., three-bladed sheet steel fan driven by a  $1\frac{1}{4}$ -in. flat belt.

The clutch is a multiple dry-disk type having eight disks. The facing rings are  $5\frac{7}{8}$ -in. inside and  $7\frac{5}{8}$ -in. outside diameter, giving a total area of 148.4 sq. in. The three-speed selective sliding gear is mounted directly on the engine. It is of the conventional type, with chrome nickel steel gears having a face width of  $\frac{3}{4}$  in. and a 7-9 pitch. The gearcase is of cast iron. The reductions in the gearbox are 2.8 to 1 on first; 1.69 on second, and 3.73 to 1 on reverse. New Departure bearings are used on the main shaft and plain bearings on the countershaft. The span of this shaft is  $6\frac{15}{16}$  in., which is remarkably short.

A  $1\frac{1}{8}$ -in. solid propeller shaft is inclosed in a torque tube which connects the gearset to the rear axle and takes torque on thrust. The single universal joint is inclosed by the ball joint connected to rear end of the gearset and is lubricated from the gearbox. The rear axle is a three-quarter floating type with a malleable iron center housing. The final drive is through spiral bevel gears with nine teeth in the driving pinion and

42 teeth in the ring gear. The bevel pinion shaft is mounted on two New Departure bearings. The differential bearings are Hyatt in connection with a ball thrust. The axle shafts are of chrome nickel steel.

The car is suspended on semi-elliptic springs, the rear springs being  $55\frac{1}{2}$  in. long and 2 in. wide, and the front springs 36 in. long and  $1\frac{3}{4}$  in. wide. The spring eyes are bronze bushed and provided with the Alemite attachment, this lubrication system being used throughout the chassis. The brakes are external and internal, on a common drum located on the rear wheels. The drum diameter is 11 in. and the width of the bands  $1\frac{3}{4}$  in. This provides an area of 111 sq. in. on the foot brake, which is the external, and  $86\frac{1}{2}$  in. on the hand brake, which is the internal set. The internal diameter of the drum is  $10\frac{11}{16}$  in. The steering gear is a Jacox screw and nut design. The steering wheel is 17 in. in diameter and is provided with the usual spark and throttle connection.

All electrical equipment is of Delco make. The distributor is a unit with the generator. The starter reduction is 23.8 to 1, while the generator is geared up from crankshaft in the ratio of 1 to 1.5. The battery provided is an Exide, three-cell type, with a capacity of 80 amp.-hr. at 10-amp. discharge rate. The head lamp candlepower is 21, and dimming is effected by a coil on the switch. A 5-candlepower tonneau lamp and 2-candlepower tail and dash lamps are provided.

All of the bodies are of the low-hung type. The car can be turned in a 36-ft. circle. The standard color is black with a white stripe around the top on the open models. The closed cars are equipped with adjustable windshield visors, a windshield cleaner, dome light, ventilating windshield, adjustable windows and sun-shades for the rear windows. All models are equipped with non-glare headlight lenses and all are provided with a tire carrier and extra rim. The upholstery of the seats on the open models is in leather and on the closed models in worsted material. As an example of the seating allowance on the touring car, the inside width of the rear seat is 46 in. and that of the front seat 39 in. Prices are quoted f.o.b. Flint, Mich., and are as follows: Two-passenger roadster, \$935; five-passenger touring, \$975; three-passenger coupe, \$1,475; five-passenger sedan, \$1,650.

### New Automatic Wrench

THE wrench illustrated herewith, which is being placed on the market by the Edstrom Machinery Co., has several interesting features. It closes tightly on the nut automatically, and it can be operated with one hand for it can be locked in place by the movement

of the thumb of the hand holding the wrench. A positive gripping action is secured by the small teeth on the movable jaw which engage with similar teeth on a sliding lug within the handle. This lug is controlled by the thumb lock, a movement of which forces the lug against the teeth of the sliding jaw, thus holding it securely. The head of the wrench is not excessively large and will fit in many places where a standard open end wrench can be used.

# A New Design of Plain Tube Carbureter

Latest design of Holley is of simple construction and arranged for easy application by universal features. Air bleeding device adjacent to throttle provides for idling and low speed conditions, large venturi for high speed.

**A** NEW carbureter of very simple design and incorporating a number of features of interest is being produced by the Holley Carbureter Co. The new carbureter has been simplified in a great many of its features by the elimination of a number of small parts. There are no moving parts. It is of the plain tube class and has but one master nozzle, which controls the flow of fuel for both idling and running with wide-open throttle.

With this class of carbureter it has been quite easy to make a motor idle or to run with the throttle wide open at full power, but the main difficulty has been in the smooth transfer from idling to the time when the main nozzle commences to contribute its proper proportion of gasoline. The transfer from idle to the full functioning of the main jet should be made smoothly and economically, since about 90 per cent of the driving is done in this range.

The two holes located above and below the throttle plate when the latter is nearly closed give this control. On idling, the upper hole only supplies the mixture, the lower one acting as an air bleeder. As the throttle is opened slightly the bleeder action is reduced, thus maintaining the mixture proportions. On further opening, both holes are exposed to the suction above the throttle. Both act as fuel outlets to supply the extra gasoline made necessary by the larger volume of air passing the throttle.

With this arrangement the Holley engineers state that more freedom is allowed in the manipulation of such other important features as positive acceleration and large breathing capacity for high speed. It is unnecessary to limit the size of the venturi; that is, a large venturi can be used without affecting the smooth and positive operation throughout the driving range. This affords high volumetric efficiency without the compromise otherwise frequently employed to secure good low-speed performance. It should also add to the maximum output of the engine.

A number of interesting details are found on the new instrument. All of the screws are made of nickel steel to resist rust and also to prevent twisting off screws which are depended upon to hold permanent adjustments. No tools are necessary for removing the cover of the

float chamber, which is held in place by a spring lock, acting in very much the same manner as a bayonet lock, except that it is continually under tension. Another feature is the strainer, which can be easily disassembled and cleaned without removing the gasoline connection or in any way disturbing the installation of the carbureter. The strainer is cylindrical in form and pulls out at a point opposite the gasoline intake, as shown in the accompanying sectional view of the carbureter. The dirt is left on the inside of the screen, since the gasoline

passes from the inside to the outside in entering the float chamber. When removing the strainer, therefore, all of the dirt is removed with it, and the gasoline line free of any deposits which may have entered during the course of operation.

The master nozzle is adjusted by means of a needle valve which, in its effect upon wide-open throttle, has a major influence. The idling adjustment is shown directly below the flange. It is used for extreme low speed. When driving at

the lower speeds, with partially closed throttle, there is an accumulation of fuel in the well, and, upon opening the throttle, this accumulation becomes immediately available as a means of enriching the mixture for maximum rate acceleration. It will be noticed that there are no small passages leading to the atmosphere. It has been found that such passages become filled with dust and dirt, and materially interfere with the accurate functioning of the carbureter. All the air enters the carbureter through one entrance, which is always connected to a suitable stove or heater.

The carbureter is universal in that it is possible to swing the strainer and gasoline inlet connection around to any point below the float chamber and to set the choke connection to be controlled from either side, or from any direction. The carbureter can be readily cleaned by removing the nozzle from the bottom. No gasket is required. These features, taken in conjunction with the simple construction of the carbureter, give a very accessible layout and permit installations on any type of engine. The carbureter is at present being manufactured in 1-in., 1¼-in. and 1½-in. sizes, top outlet, and a series of side-outlet carbureters will soon be in production.

Sectional view of new Holley carbureter

# The Design of Wind Screens for the Rear Seat

How an insistent demand for better protection of passengers from the weather is being met in England. The tonneau wind screen is likely to become standard equipment on many British cars in the near future.

By M. W. Bourdon

**A** DEMAND is growing in strength in England for the inclusion of a rear wind screen in the standard equipment of open four and five-passenger cars and, as mentioned in AUTOMOTIVE INDUSTRIES at the time of the last Olympia show, two British makers (Phoenix with a medium-priced car and Lanchester with an expensive one) have already complied. There seems to be more than a possibility that other makers will follow suit and it only requires two or three more well-known firms to adopt this policy to cause this form of protection for the rear passengers to become generally recognized as needful and rule out any car not so equipped as not being considered "ready for the road."

The demand in question applies to medium and high-priced cars at the moment, but obviously it is only a matter of time and example before rear screens are looked for on the lower priced vehicles. Clearly, the inclusion in the standard equipment of this additional item must add somewhat to the price of the car, but it should not do so to anything like the extent of that which now occurs when a buyer—as is very often the case—orders a rear screen as an "extra" or obtains one as an accessory for an existing car.

Rear screens in one form or another, all ostensibly capable of being fitted to almost any car, have been available to and used by a great many British motorists for at least 10 years past, but, as inferred above, these fittings have been relatively costly to install, and it can hardly be said that their design has been without reproach. They have been effective in their main objects, but more or less unsightly encumbrances when out of use.

The point arises, therefore, whether these objections as to cost, design and appearance cannot be overcome when the fitting is provided for in the original design of the body work. As shown hereafter, one British

maker, Lanchester, has gone a long way in the desired direction by making the screen fold up neatly, out of sight, when it is not required. The Phoenix rear screen, however, still has the appearance of being an attachment, or an afterthought.

In view of the foregoing facts and possibilities it is of interest at the present time to survey the various forms of rear wind screen now available to British motorists, and the accompanying sketches of most of the different types now being made have been prepared with that object. The types illustrated may well be grouped into five distinct classes, as follows:

Group A. Single non-folding panel screens, adjustable as to rearward inclination and secured either to the back of the front seat or to a rear cowl.

Group B. Single panel with "wings" supported by hinged or telescopic extension arms secured to the back of the front seat. Can be folded up behind front seat when not required.

Group C. Multiple panel supported by vertical pillars, one at each side, two of the panels forming wings. Can be detached, but not folded completely down below top line of body.

Group D. Flexible panel without wings, readily detachable, on light framework, supported by vertical pillars.

Group E. Single panel with wings; "built into" the body and folding out of sight.

Referring to the illustrations, one example of each of the alternatives in group A is shown. In Fig. 1 the single panel, secured to the rear top edge of the front seat, can hardly be effective except in the case of "close-coupled" bodies. When, as illustrated, it is fitted to a normally dimensioned body, the degree of protection afforded to the rear passengers can hardly be held to justify the cost of the fitting. True, it is better than nothing with a head-on wind—though only slightly bet-

Fig. 1

Fig. 2

Group A: Non-folding single panel type

Group B: Single panel with wings, supported by extension arms to back of rear seat.  
 Fig. 3—Auster      Fig. 4—Another method of supporting Auster screen      Fig. 6—Phoenix  
 Fig. 5—Beatson      Fig. 7—Perfecta

ter under that condition, and no better with a side wind. But if a screen of the same simple type be fitted at the back edge of a rear cowl, the latter extending as far rearward as the doors and hinged to the back of the front seat as in Fig. 2, Group A, this type of screen becomes worthy of consideration. The writer had a good deal of experience with two cars thus fitted before the war and found the rear seat occupants were, with the screen raised, as well protected as those at the front. If desired, in warm weather the panel can be hinged forward to lie horizontally over the cowl, and the latter itself with the screen attached can be made easily detachable from the car.

The objection to this arrangement is the slight difficulty and delay experienced by the rear passengers in getting into and out of the car. Obviously the back end of the cowl must be lifted up, and if this be done hurriedly and without care there is risk of damage, either to the heads of the front seat occupants or to the glass of the screen—for if the front seat be vacant the top edge of the screen will make more or less forcible contact with the steering wheel. There is need, therefore—or at any rate it is advisable—to fold the screen forward to a horizontal position over the cowl, and secure it thus, before the cowl is lifted.

Then, too, unless the cowl is only very slightly above the top edge of the body when it is resting on the doors—that is to say—unless it is nearly flat, its sides encroach more or less upon the doorway when it is raised to a vertical position. This was found to be a serious objection in the cases referred to, but in these days, with higher sides to the body in relation to the seats (on British cars, at all events) this difficulty is almost automatically overcome, for the cowl can be almost flat without making a high screen needful to bring its top edge level with the passengers' heads. This suggests that

there is call for compromise where the body sides are somewhat low, or the seats relatively high, in endeavoring to provide the required height of the top edge. A deep screen is to be avoided—it should be appreciably less in height than the cowl measures in fore and aft length, otherwise the latter cannot be lifted when the screen is horizontal—and the cowl should not be much above the body line for the reason already mentioned.

Despite the drawback referred to and the somewhat permanent nature of the arrangement, which prevents it from being folded right away, this scheme has points of advantage over the alternatives. It should be comparatively low in cost if standardized; it is certainly effective in the case of head winds by reason of the screen panel being near to the passengers, and in side winds it affords quite as much protection as can reasonably be demanded. It does not prevent the passengers from using rugs, and the cowl keeps off those swirling blasts which normally circulate around the passengers' feet.

The cost in low-priced cars (and the weight in all) could be reduced by using non-inflammable celluloid instead of plate glass, though additional framing and a central support would be required. This form of transparent material for the panels is already in use in other types of rear screens and is not objected to by people with limitations on the score of price. The cowl could be made and fitted quite cheaply in quantities if the front seat back were designed and shaped with the addition in view.

Turning now to Group B, Fig. 3 shows an early example of this type, the Auster. The extending arms are supported by brackets secured to the front seat framing under the upholstery or at the top of the rear panelling—usually the former. The central glass panel is adjustable as to inclination and when moved carries

Group C: Multiple panel type, supported by vertical pillars, detachable but folded below top line of body

Fig. 8—Special arrangement made for an Armstrong-Siddeley owner

Fig. 12—Another Auster design

Fig. 10—A new Auster design

Fig. 9—Straker-Squire

Fig. 11—A variation of new Auster design

the wings with it, though the latter can be swung inward or outward without moving the main panel. They are held in position automatically by the teeth of the spring-backed hinge plates. The apron or rug is attached to the screen by turn-buttons and, of course, moves with the panels. Fig. 4 shows a variation in the method of supporting this type of screen, suitable for use when the front seat framing is rather light. Fig. 3 shows metal framing for the glass and Fig. 4 mahogany framing. As regards the prices at which these two types are sold in England, the metal framed pattern is approximately \$75 (at normal exchange) and the other \$50. The former is made with panels of various dimensions, while the latter is supplied in one size only as follows: Center panel 32 in. wide, wings 14 in., arms allow extension of 20 in. from back of front seat.

Another popular "accessory" rear screen (the Beatonson) is shown in Fig. 5. This also is in Group B and differs from the Auster in the method of support. The two illustrations showing the screen in use and folded are practically self explanatory; it need only be said that this design does not allow of the main screen to be used other than vertical and as a means of deflecting the wind over the passengers' heads is not so effective on account of that shortcoming. At the same time the back draughts are not excessive, no more so than those arising from the usual windshield—especially when the permissible length of extension arms is such as to bring the panels close to the passengers.

Fig. 6 shows the standardized rear screen used on Phoenix cars. Except for the bracket supports instead of pillars it closely resembles the Beatonson. It has mahogany framing for glass panels; the waterproof apron is included with the screen in the car's equipment.

Telescopic extension arms are used in the Perfecta (Fig. 7) and the arms are supported by a central bracket

attached to the front seat frame. In this case also there is no provision for inclining the main panel. As might be surmised this screen has to a pronounced extent the great failing of extending rear screens in general, i.e. the lack of rigidity due to the distance of the screen from its point of support. In some cases this weakness is extremely disconcerting to say the least, and the blurring of the view when the glass is other than perfect or spotlessly clean is very trying to the eyes.

This type in general is not sightly; it is, in fact, considered by many people a mere makeshift, an obvious after thought, and they bear with it only because it is more or less effective in meeting a definite requirement. There is no question but that it "spoils the lines" of many an otherwise shapely car outline. It certainly is not to the credit of those who have catered for this class of fitting that for so long they have seemingly made no endeavor, not until recently, to improve upon it.

In Group C the first illustration (Fig. 8) shows an arrangement specially made for the owner of a close-coupled Armstrong-Siddeley four-passenger car with separate sliding front seats and one door on each side at the front. This design, and that shown in Fig. 9, which is quite similar, has the merit of a neat appearance, and is, according to the owner, quite effective, the gap between the center panels in this particular case is said not to permit any draught worthy of mention to pass. The vertical standards of the panels in Fig. 9 are set slightly farther back, which should be of advantage, the gap thus allowed between the screens and the front seats being fitted with short "aprons" secured by snap buttons.

While in both the cases just mentioned this type is fitted to a close-coupled four-seater with front doors only, the principle is applicable to normal body designs, and that it has openings for variation is evident from

Group D: Flexible panel type without wings, supported by vertical pillars. This type is readily detachable

Fig. 13—A single example of this type

Figs. 10 and 11. In the former the four panels are inside the body, the outer ones are clipped together at the back of the framing to prevent rattle and lend additional support. The apron is divided, half attached to each pair of frames. At present the maker (Auster) is providing pillars which can be vertical only, but there is no reason why with slight modification of the supporting brackets they should not be made adjustable so that the screen as a whole could be inclined rearwardly if that were found desirable.

In Fig. 11 there are, as seen, six panels supported by two side pillars. This arrangement is practically the same as in Fig. 10 plus side wings, though the framings are of metal in place of wood. In both cases the pillars are secured to the side framing of the body just behind the door by clips and screws top and bottom.

Another Auster design, Fig. 12, is the same in principle as the last four mentioned screens, but has modifications that hardly make it appeal to the aesthetic sense, whether or not it be considered more effective in practice. And even in the latter respect, in providing universal adjustment, the maker has perforce lost that rigidity, the lack of which is a decided shortcoming in his original and still standard pattern—the extending screen in Fig. 3. The only advantage secured by the decidedly unsightly bracket, levers, etc., in Fig. 12 is that the screens with their individual aprons can be folded down to the body sides as suggested in the lower view; but even when there the screens spoil the appearance of the car and should certainly be capable of being supported at a lower level.

The solitary example of Group D (Fig. 13) is decidedly crude in detail design whatever may be said for the principle involved. But for cheap cars it has possibilities which seem to warrant reference to its constructional features. The lateral strip is of fabric with inset non-flame celluloid panels and is supported by one horizontal and two vertical "irons" which pass easily

through wide hems or pockets at sides and top. The side supports have grooved "acorns" screwed on at the top and cranked lower ends with integral pegs and hand grips or wheels, the pegs being tapered with square tips to fit into sockets attached to the body. Thus the side pillars can be swiveled around a center formed by the peg and located in one of four positions by the squared peg and socket; this arrangement forms a tensioning device for the fabric strip, the top bar having forked ends to allow of this lateral extension.

There are four sockets for attaching to the body, two for normal use and two attached in front of the doors so that the side pillars can be located and the screen held out of the way when passengers are to enter or alight. The second sketch shows this alternative position. When the screen is not required it can be removed and dismantled, the rods being withdrawable so that the fabric strip can be folded and stowed away under the seat cushion or elsewhere.

There is no locking device to hold the tapered pegs in their sockets, the weight and the tension on the fabric sufficing to keep them from jumping out of place on rough roads. At all events the latter is the case when the screen is new and properly dimensioned; but there is a lack of precision and scope in the tensioning arrangement which suggests a state of affairs where the fabric strip is loose or yet cannot be stretched enough for the next position of engagement of the squares to be reached. In this respect there is room for improvement and also in regard to the connections between the ends of the upper bar and the side pillars.

This form of screen is not, of course, to be considered seriously as a fitting for an expensive car, but if there arises a universal demand for rear protection on all cars it has the foundations of a practical form which could be made and fitted at a very low cost.

The last two illustrations showing examples in Group E come into a category at the other end of the scale. Fig. 14 indicates the scheme devised by a coach builder for a custom-built body and is lacking in certain respects, much as it might be commended for its folding-up-and-stowing-out-of-sight feature; it is too cumbersome and heavy, and too far forward. The last mentioned fact results in the disadvantage of all rear screens which are close behind the driver, i.e. the incessant and excessive back draught which they cause the driver.

The Lanchester arrangement (Fig. 15) is a far more desirable fitting from every point of view. When in use it consists of a single panel hinging screen with wings secured to what has the appearance and effect of a rear cowl. But the whole can be instantly shut down and folded away to form the back panel of the front seat, the underside of the cowl portion is covered with cloth and appears quite normal when it serves its secondary purpose. The cowl, it will be seen, is carried by two pairs of pivoted arms of flat section steel; the top pair lie horizontal when the screen is erected and prevent the rear

Fig. 14

Fig. 15

Group E: Single panel with wings, arranged to fold out of sight in body.

Fig. 15—Lanchester

edge of the cowl from sinking beyond the horizontal, and the front edge from lifting, by reason of their resting upon "stops" formed by the top end of the lower pair of arms. To fold the cowl away the rear edge must be lifted, weight imposed upon it being resisted by the lower pair of arms in tension. Obviously a little care is needed in laying out the design and in fitting to insure that a jamb does not occur in the pivoting of the arms; otherwise the system of supporting the cowl and screen is as simple as it is effective, though it needs a slight measure of side support to prevent lateral sway. This is afforded by the closed doors of the car.

Every benefit of the cowl and screen system of Fig.

2 is provided by this Lanchester system and at the same time it overcomes practically all the objections raised against the other; it is not unsightly in use or out of use, like those rear screens with extending arms and is even more readily collapsed when required. There is nothing in its fundamentals which necessitate its being costly to make and can be easily adapted to quantity manufacture as a standard attachment. As a stock accessory for fitting to existing cars it is not feasible; but that is not what is called for, so the writer takes it, by those firms who are looking out for a simple and satisfactory form of rear screen to adopt and add to the standard equipment of their cars.

## New Standard List of Machine Screws

IN line with the general tendency toward standardization and the elimination of unnecessary parts in the mechanical industries, the Bureau of Standards and the National Screw Thread Commission have been consulting with manufacturers of machine screws for the past several years with a view of standardizing the product of this industry and eliminating unnecessary sizes. A temporary organization of machine screw manufacturers was formed for the purpose at the suggestion of the Bureau of Standards, which was joined by the manufacturers of more than 90 per cent of the product of this industry, and at a meeting held at the Engineering Societies Building on May 18 the recommended list of the National Screw Thread Commission was unanimously adopted.

In the new list, issued on June 15, a considerable number of unnecessary sizes and pitches are done away with. There is a fixed pitch for each diameter in both the coarse and fine thread. The coarse thread pitches are the standard, and screws of these pitches will be carried in stock by manufacturers. The coarse pitches are substantially the same as have been in use for a great many years and no change in shop practice or tools is necessary. Fine thread screws will be made to order only, but as the wire for them will be carried in stock, it will be possible to deliver them on short notice. Sizes in the fine thread series, for which a particularly strong demand develops will later be considered for manufacture on a stock basis.

The most important change from the old list consists in the elimination of numbered sizes above No. 12. All

machine screws above No. 12 in the new list will be in fractional sizes and confined to the coarse and fine thread pitches, which meet all manufacturing requirements. The standard sizes are shown in the accompanying table.

## Ample Supply of Wood Wheel Material

THE "American Lumberman" prints this question from one of its readers and a reply. This is interesting, as it will correct a belief apparently prevalent in the automotive industry:

In talking to an automobile salesman recently about the superior qualities of wooden wheels for automobiles as compared to wire wheels, he rather dolefully said that the public would have to get used to metal wheels soon, for it is now almost impossible to get the hardwood with which to make such wheels. I am wondering if this is correct.—Inquiry No. 206.

[Hickory is one of the best woods for automobile wheels, and there is no immediate danger of the exhaustion of hickory. So far as can be judged from present conditions, it will be one of the last woods of this country to fail in supply. Much is used for handles and vehicles, but it grows rapidly. It is at least as much of a domestic tree in its habits as black walnut, and grows along fences and in old fields where it is at its best. It is peculiar among woods in that the faster it grows, the better it is. Second growth—that is, fast-growing hickory—is preferred for many purposes. The wide rings of spring wood which are found in open ground hickory trees give a strength and toughness, exactly what is desired by makers of vehicle wheels. It will be a long time in the future before automobile makers cannot get wood for wheels if they want it.—Editor.]

THE preliminary work in connection with the opening of aviation routes across the Sahara desert has presented many difficulties, but most of them appear now to have been overcome, and it is announced that a military route is being organized from Dakar to Bamako and Timbuctoo. Every 1000 kiloms, a center is being established where, in addition to stores, there will be every convenience for carrying out repairs, while smaller stations with stores and maintenance facilities are being arranged every 250 kiloms. There will be landing grounds every 50 kiloms. The route from Dakar to Timbuctoo appears to offer far less danger than the one from Southern Algeria, where the efforts to create a service across the desert have so far failed. It is remarked that prospecting work has been carried out over the Dakar route for many months past without a single accident.

# Grinding in the Automotive Industry

## Part I—Abrasives and Grinding Wheels

In this, the first of a series of articles, the author describes the various kinds of grinding wheels, pointing out the difference in material used. Factors governing the selection of wheels, cutting speeds, balancing, truing, and troubles in grinding are among the items covered.

By P. M. Heldt

**G**RINDING has undoubtedly been practiced ever since metallic cutting tools were first used. The original abrasive was sandstone, which was found ready for use in nature, except that it had to be worked into the cylindrical or other shape required. As it is relatively soft stone this was not difficult. Later on other natural abrasives came into use, including emery and corundum. Emery was the basic material of grinding wheels for a long time, and the word "emery wheel" became so firmly established in the vocabulary of the machine shop that even to-day all grinding wheels are commonly being spoken of as emery wheels, although the proportion of wheels now made of emery is very small. The proper term to use is "grinding wheels."

Emery and corundum are minerals containing a fairly large percentage of aluminum oxide ( $\text{Al}_2\text{O}_3$ ). Emery is merely an impure form of corundum. For making grinding wheels, the mineral is ground or crushed, separated into grades of fineness by screening, mixed with a binding material or bond, formed into the shape required and "burned" to impart to it the tenacity needed by a body subjected to high speeds of revolution, and to mechanical pressure and even shock. Emery and corundum are mined in Asia Minor, India, Ceylon and Canada and in the United States in Massachusetts, North Carolina, Georgia and Montana.

About 20 years ago artificial abrasives came into use. The reason for this was that the natural abrasives did not always come in the desired degree of uniformity. Emery contains up to 64 per cent of aluminum oxide, the rest being impurities. Naturally the value of the mineral as an abrasive varies with the nature of these impurities and inversely as the proportion thereof. The chief impurities in emery are amorphous alumina, silica and iron oxide. Moreover, the aluminum oxide itself appears to exist in several allotropic forms, the highest forms being those represented by the ruby and sapphire. Corundum is composed of aluminum oxide to the amount of 92 per cent.

### Two Kinds of Abrasive

Artificial abrasives are a product of the electric furnace. There are two general kinds, one composed chiefly of aluminum oxide and the other of silicon carbide. The former kind, the aluminous artificial abrasive, was first produced by the Norton Company whose trade mark name for it is Alundum, while the silicon carbide abrasive was first produced by the Carborundum Co., whose trade name for the product is included in its corporate name. The basic patents on the processes by which these products are made have now expired, and both classes of abrasive are made by about a dozen different concerns, each using its own trade name.

Aluminous abrasives, of which alundum is the prototype, are made from the mineral bauxite found in large quantities in Arkansas, from which metallic aluminum is also made. The mineral is fused in the electric furnace and cast into pigs, which are then crushed between jaw crushers and rolls and sized by means of screens. The fineness of grain is indicated by a number which denotes the number of meshes to the inch of a screen which will just pass the grains. The mesh or grain size varies from comparatively small numbers up to 120, beyond which there are the abrasive flours, used for polishing. Silicon carbide abrasives are made by heating in a resistance type of electric furnace a mixture of powdered coke, sand, sawdust and salt, the pigs produced being treated in very much the same manner as the pigs of aluminum oxide. Only coke and sand enter the reaction.

By varying the treatment in the electric furnace several different grades of aluminous abrasive can be produced. Thus the Norton Co. at present has three different grades, known respectively as the regular grade and grades 38 and 66. Generally speaking, aluminous abrasives are best suited to grinding high tensile materials like steel, while the silicon carbide abrasives are best suited to the grinding of such materials as cast iron, brass, bronze and aluminum. Silicon carbide is harder and more brittle than aluminum oxide, and its grains therefore break more easily under the strain imposed by the high tensile materials.

### The Bond

In making grinding wheels the abrasive material is mixed with a binding material or bond. There are quite a number of these bonds, but that most commonly used consists of clay formed into a plastic mass by the admixture of water. The material is then poured into molds, dried, shaved to size and burned or vitrified in a kiln. In preparing the mixture, all of the ingredients are weighed, so as to accurately maintain the correct proportions. After burning the wheels are trued, tested for strength and inspected.

Other wheel bonds consist of sodium silicate (water glass), shellac and rubber. Silicate wheels, as they are known, are produced by making a mixture of the abrasive, silicate of soda and certain other ingredients, thoroughly intermixing them, ramming the mixture into a mold, allowing it to dry and then subjecting the wheels to a moderately high temperature. These silicate wheels are light gray in color.

Elastic wheels, made with a bond of shellac, are used mainly in very thin forms. The heated abrasive is mixed with the shellac in the proper proportion, the mixture is allowed to cool and is then forced into molds, either hand

Fig. 1—A collection of grinding wheel sections

pressure or hydraulic pressure being used. The wheels are then baked at a moderate temperature. These wheels are nearly black in color.

The rubber bond sometimes used consists of India rubber mixed with a certain proportion of mineral matter, to which the abrasive is added. By heating the mixture, vulcanization of the rubber is produced and the desired degree of hardness is obtained by varying the composition of the bond. Where very thin wheels are required they are cut out of sheets of the proper thickness, made in calendering machines, while thicker wheels are made by pressing the mixture into molds, the same as with the other compounds.

Each kind of bond has its special properties which render it suitable for certain classes of work or under certain conditions. Vitrified wheels, that is, wheels with a clay bond, constitute approximately 80 per cent of all those manufactured, and it may therefore be concluded that they best meet the conditions in the majority of cases.

The vitrified bond is very porous and therefore permits of a free cutting action. It is easier to obtain uniformity of quality than with some other bonds, and uniformity, of course, is a very important desideratum. Vitrified wheels are immune to the influences of water, acids and temperature changes. Aside from these important advantages there are, however, a number of disadvantages connected with the vitrified bond. The process of making the wheels is a rather slow one, requiring a period of a month. Some authorities assert that the high temperature necessary for burning the bond tends to weaken the grains of the abrasive. This is denied by others. The wheels cannot be made very thin, as they do not offer sufficient resistance to lateral strains. Moreover, in the case of wheels beyond a certain diameter there is danger of breaking in the kiln. This latter difficulty, however, has been mastered by leading wheel makers and the size of wheels is limited only by the handling facilities.

As regards the fields of adaptability of wheels with the different bonds, it will perhaps be best to enumerate the uses to which wheels with non-vitrified bonds are adapted, leaving it to be inferred that vitrified wheels are used for all other work. In the harder grades the silicate wheels are quite dense and therefore not as free cutting as desirable. The moderate baking temperature is an advantage from the production standpoint and the period of

manufacture is only about one-fourth as long as with the clay bond. It is believed by some that the sodium element in the silicate wheels is responsible for the particularly fine cutting qualities in wet grinding, insuring a smooth surface and keeping down the temperature of the work. This, however, may be due to an illusion that a soda solution which is a good cutting compound, is formed. Wet tool grinding and wet surface grinding on hardened steel is the particular field of silicate wheels, and they are specially favored when the wheels must be cup-shaped.

Elastic wheels, that is, wheels with a shellac bond, are used where the wheel must be very thin, as for cutting off stock and where the work must have a fine finish and must not be unduly heated for fear of spoiling the temper, as in ball race grinding. The fine finish is due to the elastic properties of the wheel. Elastic wheels are less porous and therefore less free cutting than vitrified wheels, and they will not stand as much heat; they are also more expensive.

Rubber bond wheels are generally made somewhat harder than elastic wheels and are used where thin wheels are required for hard work, where the pressures required might break elastic wheels. The outstanding feature of the rubber wheel is its strength, and such wheels are used wherever wheels with other bonds would not be sufficiently strong, as in some heavy snagging operations.

It will be understood that each kind of abrasive can be combined with each of the different bonds enumerated. Thus there are vitrified aluminous wheels and vitrified silicon carbide wheels; silicate aluminous wheels and silicate silicon carbide wheels; elastic aluminous wheels and elastic silicon carbide wheels, etc.

#### Abrasive Cutting Action

The bond not only determines the strength and elasticity of the wheel but also its degree of hardness or what is generally referred to as the grade. Before going into the different grades used and the need for a variety of grades, it is well to explain the general theory of grinder cutting action. The grains or particles of abrasive have very sharp edges which, as the wheel revolves in contact with the work, causes them to dig into the metal and take off chips the same as a cutting tool. As this action goes on the edges of the grains gradually become dulled and the pressure to which the grain is subjected increases in proportion. After this has been going on for some time the pressure on the grain becomes so great that the bond lets go of it, and a new grain then comes into action. It is, therefore, exceedingly important that the hold which the bond has on the grains of abrasive be exactly right for the particular working conditions. If the bond is too weak, that is, if the wheel is too soft, the wheel will wear with undue rapidity; on the other hand, if the bond is too strong, that is, if the wheel is too hard, the dulled grains of abrasive will not break away from the wheel and the latter will become glazed. To meet all conditions, grinding wheel makers furnish as many as twenty-five different grades, each grade being designated by a letter or number.

There is a specific formula for each grade, but after the wheels are burned they are subjected to a hardness test by means of a small steel tool. The resistance which the wheel shows to the penetration of this tool indicates its hardness and it is graded accordingly. In making machined parts commercially it is impossible to machine them to the exact nominal size, and it is necessary to allow tolerances. So in the production of grinding wheels no exact degree of hardness can be maintained, and all those between certain limits are classed as of one grade.

There are, therefore, four characteristics of a grinding wheel, namely, the abrasive material, the bond, the grain size and the grade or degree of hardness. It will be

readily seen what an enormous number of combinations of grain, grade, abrasive and bond are possible. For instance, figuring on five different abrasives, four different bonds, 25 grades and 50 grain sizes, the possible number of combinations is

$$5 \times 4 \times 25 \times 50 = 25,000$$

These are what might be called quality combinations. Plain cylindrical wheels are also made in many different diameters and widths and there are many wheels of other than cylindrical form, see Fig. 1, so between quality and size combinations there is an almost endless variety.

### Selection of Wheels

The selection of the proper combination, and especially of the proper grain and grade, is a problem for the grinding expert. Although certain definite rules have been established, the best grain and grade of wheel for a particular job are generally determined experimentally. From the known rules and accumulated experience a first rough choice is made. This wheel, and wheels similar to it in grain and grade, are tried out in actual work, and whichever combination gives the best service is chosen. Each manufacturer of abrasive wheels issues a table of grains and grades to serve as a guide in the selection of the proper wheels. This table, of course, applies only to the wheels of that particular maker.

The grain and grade of the proper wheel depends not only on the material of the part to be ground but also on whether the grinding is cylindrical, internal or surface. The reason for this is not immediately obvious, but may be seen by referring to Fig. 2. It will be observed that in internal grinding the width of the cut is very much greater than in cylindrical grinding, if the dimensions of the work and wheel in the two cases are at all comparable.

### Factors Affecting Grain and Grade

It may be set down as a fixed principle that for each job—the material, form and surface speed being fixed—there is a certain grain and a certain grade which will give the best results. Results, of course, are measured in terms of speed of production, quality of work and wear of wheels. If durability of wheels can be sacrificed to speed of production, a somewhat softer wheel can be used. Coarse grained wheels tend to cut faster and also to wear faster, but the limit of grain size that can be used depends upon the power available, among other things. To a certain extent the finish depends upon the grain, but a fine finish can be obtained with a coarse grained wheel provided it is properly trued. When a wheel cuts freely it does not generate a great deal of heat but runs comparatively cool. Coarse wheels are used where it is desired to remove a good deal of stock in the shortest possible time without regard to finish. With large grains a deep cut can be taken without danger of clogging or glazing the wheel.

In finishing parts made of soft steel and certain other materials extensive use is made of combination wheels, that is, wheels containing more than one grain size of abrasive. Such wheels give a better finish than a wheel containing only the coarser grain and remove metal faster than a wheel containing only the finer grain.

One of the rules followed in the selection of wheels is that the larger the area of contact the softer should be the grade of the wheel. Thus, internal grinding calls for a softer grade of wheel than surface grinding under otherwise similar conditions, and cylindrical grinding for a harder grade. For work of very small diameter a comparatively hard wheel should be used, and a very narrow wheel also should be harder than a wider one. Sometimes, when the wheel is being run at too low a speed, particles of metal will adhere to its surface, and the wheel is then said to be loaded.

Fig. 2—Showing variation in width of cutting surface in cylindrical surface and internal grinding

Fig. 3—Norton method of balancing large diameter wheels

### Cutting Speeds

Surface speed is an important factor, and as the wheel wears down and becomes reduced in diameter its speed of revolution is often increased to make up for the reduction in its circumferential speed. In cylindrical grinding a change in work speed has the same effect. Operation at a lower speed gives somewhat the same effect as a softer wheel and often complaints are made that wheels seem to be getting softer toward the center, when the only difference is that the circumferential speed is lessened. The following circumferential speeds are recommended by the Norton Company:

Kind of Grinding	Circumferential Speed in ft.p.m.
Cylindrical grinding .....	5,500 - 6,500
Snagging and general off-hand grinding.....	5,000 - 6,000
Surface grinding .....	4,000 - 5,000
Knife grinding .....	3,500 - 4,000
Wet tool grinders .....	4,000 - 5,000
Vertical spindle surface grinding .....	4,000 - 4,500
Elastic and rubber cut-off wheels .....	9,000-12,000

### Balancing of Wheels

Vibration increases the wear of the wheel and should be kept at a minimum. It depends in part upon the rigidity of the machine and in part upon the balance of the wheel. All grinding wheels are balanced by the manufacturers, usually by chipping holes near the bushing on the light side and filling them with lead. As the wheel wears it becomes unbalanced again and must then be re-balanced by the user. The reason for this is that wheels, as generally made, are not of uniform density throughout. A wheel which is considered out of balance will cause chatter marks on the work. In rebalancing, it has been the custom to either remove some of the original lead counter weight or else, if the plane of unbalance is found to lie at an angle to the original plane of unbalance, to chip a new hole and fill it with lead. This method of rebalancing has not been found entirely satisfactory, and efforts have recently been made, particularly by the Norton Co., to devise an improved method. This development work has not yet been concluded, but one method for balancing wheels with 5 in. holes has been introduced in practice. It consists in the use of a cast bushing securely fastened in the

wheel and provided with detachable lead weights, which can be moved circumferentially around the bushing (See Fig. 3.) Balancing is done on a pair of balancing ways, the wheel being placed on an arbor which is placed on the ways. A chalk mark is made on the side of the wheel which comes to the top, and the lead balancing weights are then secured to the bushing on that side. In no case should less than two balancing weights be used. By moving the two weights farther apart, the balancing effect is reduced. It has been found a very good plan to have all balancing of wheels in a plant done by a single man who will thus acquire considerable skill in the operation. The wheels should be balanced when returned to the tool crib and also when given out again, as they get out of balance when put away wet.

### Truing and Dressing

A lathe tool must be sharpened and reforged occasionally, so also a grinding wheel must be reconditioned periodically. There are two methods of reconditioning grinding wheels, known respectively as truing and dressing. By the former the wheels are given their exact geometrical shape, while the latter method serves merely to give the wheel an approximately cylindrical form, and to roughen the surface and thus improve the cutting properties. Dressing is of little use in connection with wheels for precision grinding but is valuable in reconditioning wheels used for snagging and other rough work.

Corundum, one of the natural abrasives used in grinding wheels, is next to the diamond the hardest mineral known, and, therefore, diamonds are depended upon mainly for truing up the wheels. The diamonds used come from South Africa and Brazil and they come in various grades. Their color varies from pure white to black through all intermediate shades. In the selection of diamonds for the truing of grinding wheels, hardness is not the only factor to be considered; the hardest stones are usually brittle, and are therefore easily ruined by careless use. One maker recommends the use of brown bort stones as possessing the greatest number of desirable qualities. The diamonds are mounted in the holders either by peening, by brazing or by casting the holder around it. It is preferable that the diamond should be completely supported by the metal of the mount, without air spaces at any point, as it will then be best protected against breakage. This can best be effected by the cast mount. Either cast steel or some special metal of somewhat lower melting point is used for the purpose. Peening is a very delicate operation that requires great skill. Some grinders think that the high temperature of the molten steel injures the diamond. Whatever metal is used for a cast mount, it must contract strongly in cooling, so it will get a firm grip of the diamond. Silver solder is sometimes used for this purpose.

When a diamond is worn down to the metal setting it is reset so as to bring a new cutting surface into use. The size of the diamond should depend upon the size of the wheel. When the stone is worn down to too small a size it can be reset and marked for use in the tool room. In dressing a wheel, light cuts must be taken and the stone not jammed into the wheel. Diamonds are very hard and brittle, and for that reason must be handled with extreme care. A copious stream of water should be directed on the diamond at the point of contact with the wheel, except on the smallest sizes of soft wheels which may be trued up dry. For precision grinding the wheels are preferably trued with a diamond.

### Truing for High Finish

In truing the wheel the diamond must always be rigidly held in a tool post which by means of a slide can be

fed across the cutting face or faces of the wheel. By means of a diamond with a rounded point it is possible to true up a wheel in such a way that it will give a very smooth finish. Thus the same wheel may be used to remove metal rapidly and to give a high finish to the piece worked upon. By passing the diamond over the surface slowly, a smooth and true surface is obtained. This surface, however, is more or less unnatural on the coarse wheel, and great care must be exercised in applying the wheel to the work, so as not prematurely to disturb it. If the wheel is to be used for roughing again, all that is necessary is to take a deep cut.

For fine and dense wheels used for cylindrical grinding a sharp diamond is recommended, as this will somewhat roughen the surface, thus improving the cutting action if the wheels have a tendency to be too smooth. A round holder for the diamond is considered preferable to a rectangular one, as the holder may then be reset to a different angle at frequent intervals so as to cause the diamond to present a new cutting surface to the wheel. Silicon carbide wheels wear out a diamond more rapidly than aluminous wheels, because of their greater hardness, causing greater wear.

### Cutting Fluids

In practically all precision grinding a jet of coolant is played on the wheel close to the cutting surface, grinding machines being always provided with the necessary reservoirs, pumps and delivery pipes. The chief object of the fluid is to keep the working surface at a uniform temperature, so there can be no heat distortion of the piece being worked upon. The fluid also keeps the wheel clean and therefore free cutting. While plain water is being used in some instances, it has the disadvantage that it tends to cause the machine and the work to rust. Sal soda and lard oil or grinding compounds are added to the water to prevent rusting. Internal grinding is often done dry, because the fluid would tend to form with the chips a paste which would clog the wheel and impair its cutting action. On bronze a thin oil or kerosene is used as the cutting fluid. When grinding cylindrical work the water spout must almost touch the work and stand away from the wheel about  $\frac{1}{4}$  in., except on work having a spline in it, when it is necessary to move the spout farther away from the wheel.

### Causes of Trouble

When trouble is experienced in grinding it usually comes under one of the following five heads, and the possible reasons of each kind of trouble are those given:

Wheel does not cut—Speed too high; wheel too soft; wheel of too fine grain; wheel is not the right kind as regards abrasive used.

Wheel wears away too fast—Wheel speed too low; wheel too soft; grain too coarse; too much vibration; pressure of wheel on work too great.

Unsatisfactory finish—Grinding surface of wheel not true; surface not sufficiently smooth; machine spindle vibrating; wheel out of balance; wheel too coarse; use of vitrified or silicate instead of elastic wheel.

Wheel loads—Surface speed too low; wheel grain too fine; wheel too hard.

Wheel glazes—Surface speed too high; wheel too hard; wrong kind of abrasive.

The remedies for all of the above troubles are self-evident.

In all grinding work it is a good plan to take advantage of the expert knowledge of the organizations of the wheel and grinding machine makers in determining the best kind of abrasive grain and grade of wheel, as well as in settling other puzzling problems. In reordering wheels

the greatest care should be taken to give correctly all dimensions of the wheel, giving a sketch of the shape if same is special; the make of machine on which the wheel is to be used, the grade and grain, whether the wheel is

to be of the vitrified, silicate or elastic kind, and the kind of abrasive. It is well to always retain the tag which comes with the wheel, as this will be found a help in re-ordering.

# Combining Quality with Efficiency in Fender Enameling

Special attention to equipment and methods makes the enameling department described here worth study. Twenty-eight electrical recording instruments maintain accurate control of oven temperatures. Ovens are equipped with conveyors which carry fenders through drying process.

By J. Edward Schipper

**A**N expert enamel man can almost tell the quality of an automobile by looking at its fenders. In no other part of a car is it possible to slight the work and yet produce a passable result which in nine out of ten instances would pass inspection by the casual and uninformed observer. The average man in the automobile business or out of it who is not posted on enameling would be surprised to think that a concern would install 28 recording instruments, costing nearly \$500 apiece, for the sole purpose of maintaining accurate and exact control of the oven temperatures. This represents only one small detail of the expense which has been gone to in the enameling department utilized for the finishing of the Packard radiator shells, bonnets, fenders and a great many of the small parts for its cars.

The enameling department at the Packard factory has been laid out to produce fenders for 100 cars per day. It has been put on the two top floors of the factory; namely, the sixth and seventh, so as to be above the city's dust line. All of the sub-departments are separately inclosed in glass, so there is a minimum chance of dust circulation through the rooms where the work is being carried on, and, at the same time, good light is provided.

Parts which are to be enameled arrive at the enameling department both from the Packard company and from outside sources. It is almost true to say that in a walk through the enameling department not a brush was to be found; as a matter of fact, there are two brushes in the department. One of these is used for putting oil on a certain small part which is subsequently drilled, and the other for a purpose just as far removed from the actual enameling operation.

After the material reaches the enameling department, the first operation is preparing it for the enameling operation. The parts are boiled in potash for 10 minutes. The solution of potash is made up of 35 lb. of potash to each 100 gal. of water. This solution is sufficiently strong to clean the part ready for rinsing. The parts are then put through a Niagara washing machine, first being washed with an Oakite solution to neutralize the potash and then with clean, hot water.

Following the washing operation, the entire surface of each part is emiered off by hand and then polished on regular metal polishing machines operated by electric motors. The wheels used on the polishing machines are the No. 7 Alundum, which take off all the rough spots. This cleaning operation puts the part in condition for the priming coat, consisting of a No. 489 Arco primer, which is sprayed on. The parts are then baked for an hour at a temperature of 400 deg. in electric ovens.

These electric ovens, of which there are 16, are the product of Young Bros. They are all equipped with Palmer-Bee conveyors, so that at no time is it necessary for a man to enter an oven. The conveyors are the endless type and the ovens are double-ended, so that it is possible to load at one end and remove from the other without any waste of time; that is, the conveyor simply carries the material through in one direct line, first starting at the point at which it is loaded, making its first stop at the center position, or in the oven, and its last stop at the unloading position at the opposite side of the oven.

After the priming coat has been baked hard, the parts are sandpapered and taken to the bumping room and then back to the polishing machines. This removes all of the rough spots and irregularities detected after the priming coat is rubbed down.

After the parts have been thoroughly cleaned, dried with an air hose and wiped, they are sprayed with a coat of No. 409 Arco filler, and again baked at a temperature of 400 deg. Fahr. for one hour. They are again sanded smooth with a No. 0 "3 Mite" cloth. After this they are wiped off with what is known as a "tack" rag. This consists of a cheesecloth which has been soaked in ordinary varnish and allowed to dry until it becomes tacky. When wiping the parts with this, the tackiness of the rag causes all of the dust particles to adhere to it, leaving the part perfectly clean. This operation prepares the part for the two coats of enamel, known as first coat enamel, a 28 gravity product. This gravity has been found best for this work. Both these coats are baked at 400 deg. for one hour. They are, of course, given a low heat for a short time before the top heat of 400 deg. is put on. The low heat generally ranges about 250 deg., allowing the enamel to take a secondary flow, as during the time the parts are being hung up on the conveyor before they enter the ovens they become partially dry.

The two coats of first coat enamel are rubbed to a perfectly smooth surface with pumice, felt and water and are then washed off clean and the moisture blown off with an air hose at a pressure from 70 to 80 lb. The parts are again tack-ragged and dipped into the finish enamel. This enamel also is an Akron enamel, being mixed to a gravity of 27½.

In carrying on this work the Packard company has in its equipment 10 spray booths. Both the gravity feed and cup spray are used. The spraying device is the DeVilbiss Spray Aeron. To accurately maintain the heat of the ovens 28 recorders are installed which automatic-

1—Tank in which the parts to be enameled are boiled in a potash solution for 10 min. They then pass to a Niagara washer, which is shown just to the right of the potash tank  
 2—Cleaning fenders to be enameled on electric polishing machines with No. 7 Alundum wheels  
 3—Spray booths used for spraying on priming and finish coats of enamel. No brushes are used in the enameling work  
 4—Parts are hung by hooks on Palmer-Bee conveyors and rolled into the Young Bros. electric ovens shown herewith.  
 5—Going over the surface of the parts to be enameled and perfecting minor irregularities.  
 6—Rubbing stands for hand rubbing the priming coat  
 7—Cleaning and tack ragging enamel parts preparatory to receiving the finishing coat  
 8—Filtering tanks for enamel. Left, De Laval separator for priming coat, and right, tank with Empire separator for finish

ally control the temperature and record it. They are electrical instruments made by Leeds & Northrup of Philadelphia. They are arranged for automatically switching from low to high heat as desired. The mechanism is so arranged that it automatically times the low heat as well as the high heat, starting the oven at the temperature desired and then switching it to the higher temperature, and at the end of the desired period cutting it off.

For the preparation of the enamel there is a filtering plant equipped with a De Laval special separator for the priming coat and an Empire separator for the finish enamel. The enamel as received is pumped from the drums into the mixing tank, where it is mixed to the desired gravity with turpentine. It is then drawn into the filtering tanks, where the separators purify it, and finally it is pumped into tanks from which it is drawn

for use in the enameling operations.

At the present time this department of the Packard company is employing about 130 men and is busy with night and day shifts. This is a department which is called upon very largely for service as well as production work, and consequently is not so much affected by fluctuations in the retail business as other departments of the factory. Running at the 100-per-day schedule, the department employs about 240 to 260 men. It is distinguished by its rigid inspection and the time and care required of the men for the performance of each operation. There has been no attempt to speed up the dipping operations, for instance, as great care is used to eliminate air bubbles. Similarly, in the rubbing down and cleaning operations, no extraordinary effort has been made to shorten the time, as the work is gaged by its thoroughness rather than upon its speed.

## Some European Aircraft Items

**T**HE engine shown in the accompanying cut is said to be the highest powered single unit aircraft engine ever built. It has sixteen cylinders arranged in four blocks of four each. The angle between the lower blocks is much wider than that between the upper pair. The engine was constructed for the British Air Ministry by D. Napier & Son, Ltd. It is reported to have developed 1,057 hp. and to weigh slightly over two lb. per hp.

Below at the left is shown a view of one of the powerplants used on the Italian dirigible "Roma" purchased not long ago by the United States and turned over to the American Air Service officers sent to Italy to dismantle the ship and bring it to this country. The "Roma" is said to be the second largest semi-rigid airship in existence. It is 410 ft. long and has a cruising radius at full speed of 3,300 miles. It was purchased from the Italian Government for the sum of \$200,000, and it is said that it would cost \$1,250,000 to duplicate this dirigible in this country.

Below at the right is an unusual photograph showing the crew of the British dirigible R-33 boarding the great ship via mooring mast used as an anchorage. The photograph was taken at Pulham Airdrome, England.

# Selling American Cars in Spain

Here is a close-up on the automobile situation in Spain. It is written by a man who has just spent several years there selling American cars. He points out defects in past American methods and tells in graphic fashion the difficult conditions met with in selling to the Spanish market.

**H**AVING spent about eight months in Spain, I think I am in a position to review the present status and prospects of American cars in that country. I have made the acquaintance of dealers in all parts of Spain and have discussed their problems with them.

Spain offers one of the best markets in Europe for American cars, since it has comparatively few cars per person. Traveling through the rural districts one seldom meets automobiles, while the density of cars in the cities is similar to that in the United States 15 years ago. There are many more horse driven than motor vehicles. In other words, Spain is still virgin territory as regards the sale of automobiles. Despite the fact that there are still comparatively few cars in Spain rapid strides have been made during the last few years. There are now between 35,000 and 40,000 cars, while the population is about 22,000,000.

It is hard to understand the attitude of the Spanish public toward automobiles. Both rich and poor are antagonistic. Cars are not used primarily as a means of transportation; they are merely playthings of the rich. The poor people still consider them devil cars and throw stones at them. Many a rich man has a feeling against cars, because they scare his horses and because automobiles force more activity in the general Spanish life. To understand this attitude it is necessary to understand something of Spanish character and modes of living.

No real Spaniard is ever in a hurry. Most of them take their daily siesta, while the others at least take several hours for lunch and one or two hours afterward for coffee. Spain, in general, is many, many years behind its neighboring countries in development, and it still resists progress and new ideas. The difference between France and Spain is noticeable as soon as one crosses the frontier. In France one notices many automobiles, trucks, tractors, factories and farmers cultivating every inch of land, while on the Spanish side of the frontier one is immediately impressed by the absence of such activities and by immense areas of uncultivated country, the use of oxen, the Roman wooden plow and general lack of activity and cleanliness.

The Spanish country people do not take to new machinery. As a matter of fact, they resent being disturbed by the active salesman who tries to make them see the advantages of his product. The Spanish purchaser is by nature suspicious. He always believes that one is attempting to cheat him. The salesman who names his lowest price immediately

has made a great mistake, for the Spaniards are inveterate bargainers and always want to pay less than the price first asked. I have seen instances where it took three weeks to adjust a difference of less than 1 per cent in the price asked. We would consider this wasting \$1,000 worth of time to make \$10, but the average Spaniard considers time the cheapest commodity and regards it as worth nothing.

Before one can do satisfactory business with a Spaniard, one must have his confidence. To make one's self liked and to gain this confidence is accomplished only by slow means. It takes many weary hours' talking about the bullfight, the weather or politics before one dares to begin to discuss business with the average Spaniard. Once the Spaniard has confidence, however, one can sell him nearly anything and he will be interested in any proposition one puts up.

To foresee the future of the automobile business in Spain it is necessary to review the past. Up to the outbreak of the European war, French, German and English cars were sold almost exclusively. Very few American cars were used and American products were viewed with suspicion, chiefly because they were too cheap. The few American firms that did enter

the market went about merchandising in the wrong way. The other foreign cars were of the most expensive type, used mainly by the very rich in the cities. The cheap car was practically unknown.

During the war, when it was impossible to import cars from European countries, nearly every automobile agent tried to secure the agency of some American car. Neither the ability of the agent nor the reliability of the factory had anything to do with the establishment of relations; agencies were established everywhere. Every rich father gave his son a few thousand pesetas to set up in business as an automobile agent. Selling cars was considered the proper work of the idle rich, since it allowed the rich young men to run through the streets in their demonstration cars and have a very good time. Such agents, of course, sold a few cars and never thought it necessary to carry spare parts or give service on the few that were sold. Naturally, great harm has been done, and many good American cars now have a bad reputation in Spain.

The real agents, who were established and had service stations, had great difficulty obtaining cars from American factories. Very little attention was paid to these real agents by the Americans. Conse-

---

**M**ANY special conditions must be considered in selling cars to Spain. "No real Spaniard," the author says, "is ever in a hurry. The Spanish people do not take to new machinery. The Spanish purchaser always believes someone is attempting to cheat him. The Spaniards are inveterate bargainers."

---

quently, many of the agents became disgusted and cancelled their agencies. Others kept on and had all kinds of trouble. Cars were shipped in poor condition and not in accordance with specifications. American companies shipped incomplete cars, and the agent had to wait sometimes three to six months to get the missing parts. Notwithstanding all these difficulties, American cars won out because of their inherent merits; certainly not because of the efforts of American factories.

American cars had self-starters, electric lights, and went up any hill on high—qualities unknown in the European cars. Moreover, American cars were cheaper.

The result is that to-day about 80 per cent of the cars in Spain are American. Especially during 1920 was our business with Spain very large, although it fell off in the fall. During that year the import duty was rather moderate—one peseta per kilogram, payable in gold at a premium of about 40 per cent, while the exchange also was not greatly above normal. During 1920, moreover, the great fortunes made in Spain during the war were being liberally spent. Since then conditions have changed entirely.

In the fall of 1920 a good many of the war profiteers' fortunes had been spent. Most of the people who made this money never had been in business before and lacked the knowledge to continue their operations. Consequently, they began to liquidate their belongings; among the first to go were automobiles and pianos. Thus a great many second-hand cars were thrown on the market.

At the same time credit began to be tight. Banks refused to loan money as readily as they had before. Loans were called, and automobile dealers had difficulty in financing their shipments. The Banco de Barcelona had to close its doors. Catulana, the richest and the only industrial part of Spain, was thereby thrown into a panic. The effect on all business was instantaneous, and depression followed rapidly. To make matters worse, the Spanish Government thought to increase the declining value of the peseta by preventing imports, and on November 28, 1920, after giving 24 hours' notice, increased most of the import duties by 200 per cent.

The effect on the automobile industry was instantaneous. Ford increased the price of its touring car from 4,500 to 8,500 pesetas. The average small American car selling for 13,000 pesetas had to be sold for 18,000 pesetas. There was much confusion; everybody was trying to unload; dealers having stock before the buyers became scarce and scared. Moreover, the government unofficially spread rumors that the new duties were only temporary and would be lowered soon.

The Seville agent of a well-known, popular, low-priced car made in America, for example, sold 80 cars from Sept. 1 to Dec. 1, 1920, and then sold but one chassis and one sedan from then to April 1, 1921. All during the winter business was stopped. Spring brought no buying movement; very few cars have been sold even during the summer.

Ford, who was assembling cars in Cadiz before Nov. 28, 1920, at the rate of 25 daily, closed his factory, although I understand parts for 2600 cars were

in stock on which the duties had not yet been paid. It seemed that every month conditions were worse. All seaports were loaded with cars and trucks and agricultural machinery. Germany dumped its stocks in Barcelona, France in Irun, and England in Bilbao. In Barcelona alone I have seen over 1500 cars and trucks on the docks on which duties had not yet been paid, most of them in bad condition, tires missing, leather rotting, etc. The dealers had no money to take these cars away, the banks refused loans.

The long-awaited duty revision came last May, and, as far as I can find out, is again only provisional until such time as an international conference will establish reciprocal tariffs. The new duties, however, are about three times as much as the previous ones and practically close the Spanish frontiers. The new duties are approximately as follows:

On chassis, until 1000 kilos, 20 per cent of the value.  
On chassis, more than 1000 kilos, 30 per cent of the value.

Open bodies, 20 per cent of the value.

Closed bodies, 35 per cent of the value.

Spare parts, from 25 to 35 per cent.

All these duties are payable in gold, which means about 40 per cent premium. There is also a duty on transportation and expenses which amounts to about 5 per cent.

Small American cars can still be imported when the market opens again. I am investigating the possibility of importing parts and assembling cars in Spain, which seems to be the only chance of doing business there, although it might not be advisable until such time as the

duties have been revised definitely. Should this be possible, it might mean large business.

As regarding the future of consumption of the Spanish automobile markets, I believe that Spain will some day take a large number of American cars. It is doubtful how soon this will be, but the time will come. A good deal, of course, depends upon how strenuously and intelligently the American manufacturer develops this market.

The use of automobiles in any country, however, depends a good deal on the following factors:

1. Conditions of roads.
2. Facilities for the use of cars.
3. Popularity of cars.
4. Financial ability to purchase.

The situation in Spain as regards these factors can be readily analyzed.

#### Roads

The roads in Spain are atrocious. There is one rather good road from Irun, San Sebastian, to Madrid, but woe to the poor motorist who goes anywhere else, especially during the fall, winter and spring, when considerable rain has fallen. The roads are a continuous series of mudholes. I have seen a real lake of mud on the main road from Madrid to Barcelona, 20 miles before entering the latter. In the South the roads are generally bad, very rutty in the rainy season and dusty in summer. In the summer, dust is an inch deep in most Spanish roads, and in the winter one usually has as much mud on the

top as under the mudguards. The Spaniard knows, however, how to make good roads. A few years ago a new road was built over the mountains, near Seville, of which any country might be proud, but usually good roads are the last thing the politicians think about, and, when they do, the coffers are empty. There is absolutely no public demand for good roads; the newspapers never mention them, and the term "good roads" is practically unknown.

The present roads consist mostly of clay. They date back to the time of the Moors, and are very broad and flat. There is no foundation to most of the roads and water will not run off them. New surfaces are made by dumping stones on top and crushing them down with a road roller. Sometimes a roller is not used, and the stones are allowed to lie until they are naturally crushed into the old surface by the traffic. Mule carts, with very large, thin wheels making a wide track, constitute the bulk of traffic on Spanish roads. It is possible to go 500 miles without meeting one automobile, and the passing of a car through any village is an event. So far as I know little road improvement is contemplated by the present government.

### Facilities

The facilities for the use of cars are so poor as to be almost unbelievable to the average American. In the few big cities there are garages and shops, but only in Barcelona and Madrid is one able to get tires of all sizes. In Madrid, as well as in other cities, gasoline is sometimes very difficult to obtain. In the garage where I kept my car, for example, it was frequently necessary to make a daily allotment of two litres per car because of lack of gasoline. This was mainly due to railroad conditions, which are rather deplorable in Spain. Gasoline is always sold in cans of 5 to 18 litres, costing about \$1 per gallon. The quality is poor.

Most of the gasoline is refined in Bilbao and other seaports, and the supply is mainly controlled by the trust, which maintains prices, and cannot yet see that cheap gasoline would increase the use of cars. Most of the small cities never have gasoline at all, while those that do have it sell it by the bottle in drug stores. In Granada, for instance, a city of 100,000 people, I was forced to buy gasoline last spring in a drug store and pay nearly \$2 per gallon. In the villages cars are unknown and garages are, therefore, scarce. There are sometimes distances of over 150 miles without anything in the way of gasoline, oil or supplies, but one gets used to this condition and takes everything along. Accessories in Spain are very antiquated, and even in Madrid I could not find one shop where they were really in a position to repair a generator. Electricity, as far as automobiles are concerned, is still in its infancy. All of this makes motoring rather difficult and expensive in Spain and naturally hinders sales.

### Popularity

As far as popularity of automobiles is concerned, I have already discussed the unpopularity of automobiles in the cities. The average man in the cities, perhaps, has the idea of owning a car sometime, but in the country people don't see why anybody should have one. I believe if a doctor in a small village would purchase a car he would lose his clients, unless he could immediately prove its utility.

Owning a car in Spain means being so wealthy that one can throw the money out of the window. The automobile is not considered as a means of transportation at all. It is still an article of luxury, and I am afraid it will be so for a long time to come.

It is true that Ford has made some inroads on this theory, and, by placing agents throughout Spain in even the smallest cities, has succeeded in at least making the Ford car be used as a transportation medium. In the cities the distances are not very large, and business men have not yet learned how to use a car in their business activities. Furthermore, the use of a car in the big cities is something of a nuisance and rather dangerous. The Spanish people since time immemorial have been used to walk in the middle of the streets. The average Spanish street is narrow, and the people will not change their habits for the automobile. There have been so few real accidents in the big cities that the people do not realize the danger of cars. On the business thoroughfare it is not unusual to see a man cross the street reading his newspaper and no amount of sounding the klaxon will make him budge. It is also rather dangerous to leave one's car outside unattended; usually one finds his tools or spare tire gone. Cars are seldom stolen. There is a special purpose in stealing spare tires. They are sold in the country, where they are cut up in sections the lengths of shoes and used as shoes by lacing the ends together over the foot.

Another thing which makes motoring in the cities unpleasant is the police activity. To explain this, let me first explain the licensing of cars. Inasmuch as all cars are imported, in order to license one it is necessary to have a receipt of the customs house, furthermore a bill of sale, then to make an application to the governor of the state in which one lives. Then after a while the car is inspected by the government engineer. With his certificate, one has to go to another office and wait until they give the number of the license. Then one has to have the plate made. The shortest time on record for accomplishing these formalities is eight days, but usually they take two or three weeks.

The license number has the first letter of the province in the front, so if one goes from Madrid to Barcelona, in order to drive there one has to get a special permit. Of course, the price of all this is high. Dealers have recently obtained the privilege of licensing their own cars without paying the taxes for same and, later on, when the car is sold, transfer the number to the customer, who will pay the tax. The trouble is that the municipal police, probably on instructions from men higher up, do not recognize these licenses and make all kinds of trouble. They told me several times that mine was only good from 6 until 10 in the morning in the park, after that the car had to go to the garage. Once when I had left it in front of a theater at night, they actually paged me and forced me to take it back to the garage.

Life is rather dull in Spain, however, and little things like this make it interesting. After the killing of Sr. Dato by some syndicalists on a motorcycle, the order was given that no car leave Madrid without a special permit. I had a demonstration to give in the country, but with my dealer's license there was no way of getting out. It took everywhere from one to three hours to get the permit, which was only good for that special day. This made it rather hard on people living in the country and coming to Madrid every day. This order has since been revoked, but a new one is in effect, and within a circle of 100 km. from Madrid there are from five to seven police posts, stopping all cars, forcing everybody inside to show passports. The owner must show his license, and the driver his driving permit. This is supposed to be all written down on special blanks, but inasmuch as most policemen do not know how to write their own name, and the blanks

are usually missing, I have seen them write the information down on the edge of a newspaper.

Another point of difficulty is the filling of cars with gasoline; I have seen three pumps in all of Spain. The other places all use cans, an extremely slow method. Tire pumps are practically unknown; free air does not exist. When my cars arrived in Cadiz it was impossible to find a garage that had even a hand-pump which would work.

#### Ability to Buy

An examination of the financial ability of Spain to purchase cars indicates that there will never be as many cars to the population as in the United States. There are three classes in Spain, the rich, the middle class (shopkeepers, etc.) and the working class. The others are mere beggars. The term working class includes the farmers. Farmers very seldom own their own land and, when they do, are not progressive enough to make it produce on a large scale. They produce just sufficient to keep themselves alive. The rich class purchases cars, the middle class very seldom makes enough money to do so and the working class never will. Even when salaries were highest, workmen made about 15 pesetas daily, or \$2, which is not enough to even buy a car on installments, especially considering the large size of the average Spanish family.

At present there is no purchasing power in the country. Credits are curtailed and there is a great crisis in all industries. Textile factories, mines and a great many other industries have no work to offer. Due to the duties and also to monopolies, prices are exceedingly high, and the country is really passing through a severe period.

Notwithstanding all these unfavorable circumstances, I foresee a great future for the American exporter of automobiles in Spain. As soon as exchanges are more normal our prices will be such that no French manufacturer can compete. The French have lost much ground and will lose more. Some day or other the normal trend of business will come back. Spain may have to go through some severe disturbances before this normal period arrives, but it is bound to come, nevertheless.

Spain, in my opinion, is the richest country in Europe. It has every natural advantage—climate, soil, minerals of all kinds, gold, silver, iron, copper, marble, sulphur, etc. It has enough water power to carry on its industries without ever using another ounce of coal. At present, however, it has enough coal to supply its own needs and to export a considerable tonnage, provided the Spaniards would work. Last year, nevertheless, they had to import coal. What Spain needs is to wake up and go to work. This will not occur, though, for many years to come. Spanish capital is not interested in developing its own industries. The average Spaniard with money will buy bonds and live on his own income rather than ever do any work again. Foreigners must bring in their money to develop the country's resources. This is being done on a large scale and very successfully, as in the Rio Tinto copper mines. There are more opportunities in Spain to-day for foreign capital than in any other country in Europe or elsewhere.

American automobile manufacturers, if they desire to sell their products in Spain, must see to it themselves that they have the right kind of agent. Agents should not be appointed by correspondence. Once the manufacturer has such an agent, he should support him in every way.

One great disadvantage in Spain to-day with regards to the development of the automobile business is the more or less antagonistic attitude of the newspapers, the press, which has not yet realized the value of motor cars. Automobile accidents have headlines, with photographs, long descriptions and many sarcastic remarks about the danger of automobiles. But the papers never will make a favorable remark about a dealer's product, regardless of extensive advertising. I did, however, succeed in getting one Madrid paper to issue once a week a special page on automobile activities. American manufacturers should realize that by assisting their agents in this line they would be working for their own prosperity.

#### Foreign Cars in Spain

A detailed list of car registration in the districts of Seville, Spain, from March to June, 1921, presents an interesting side light on the foregoing article. This list is taken from the records of the Royal Automobile Club of Spain. The total of new registrations was 95, of which 40 were American and the remainder of manufacture in European countries. The foreign makes registered were:

Hispano	Renault	Ardic
Peugeot	Berliet	Union
Mercedes	Dixie	Sizaire
Excelsior	B. S. A. M.	Steyr
Citroen	Brennabor	Turcat Mery
Fiat	Rolls Royce	Unic
David	Charron	Itala
O. K. Junior	Stoewer	Rex Simplex
Hansa Loyd	Cormen	Benz
N. A. G.	Dion Bouton	Arbenz
Doby	Dux	
Rochet Schneider	Wolseley	

These thirty-four makes are of interest as showing the competition. The American makes were:

Wichita	Maxwell	Briscoe
Buick	Gardner	Cleveland
Hupmobile	Oakland	Ford
Paige	Studebaker	Overland
Haynes	Hudson	Chandler
Merced	Dodge	King
Essex	Crow-Elkhart	Stutz

The number of American makes was 21—Overland with 7, the N. A. G. with 5, Fiat with 4 and Dodge, Citroen and Peugeot 3 each, were the leaders.

The gasoline price given was .80 pesetas per liter—or 60 cents per gallon at normal rate of exchange.

#### Packing and Crating Automobiles for Foreign Shipment

**M**ETHODS of packing and crating automobiles and trucks for foreign shipment have not yet been standardized, but excellent methods have been developed in the practice of certain concerns with considerable experience in this field. One chapter of a new book entitled "Export Packing" by C. C. Martin takes up the crating of cars and trucks and is illustrated with photographs of the packing used by several companies.

The volume is published by the Johnson Export Publishing Co. and is designed as a general guide for crating for foreign shipment. It is of considerable bulk, but has special reference to automotive work only to a limited degree. The author was assisted in writing several chapters by D. T. Abercrombie, formerly Lieutenant-Colonel of the Quartermaster Corps; H. N. Knowlton, formerly Captain in the Ordnance Department, and M. C. Fitzgerald, Manager of Transportation, General Electric Co.

# Status of American Motor Vehicles in Japan

There are about 9000 automobiles in Japan. 70 per cent of these are American made. High import duties on finished cars have caused large importation of parts. Most bodies are made within the country. Special packing methods and other merchandising factors are discussed.

By Lester Schnare\*

**D**URING 1920 1745 automobiles, valued at \$2,425,518, and automobile parts to the value of \$2,798,141, were imported into Japan. The total value of automobiles imported in 1919 was \$2,757,473 and the value of automobile parts was \$2,866,754. The number of automobiles imported in 1919 was 1579, which indicates that a larger number of medium and low priced cars were imported in 1920 than in 1919.

The value of automobiles and parts imported from the United States was \$5,405,818 in 1919 and \$5,015,130 in 1920. Italy exported automobiles to Japan amounting in value to \$138,041 in 1919 and \$9,889 in 1920. No other country had an important share in the Japanese automobile imports in these years.

In recent years the value of the automobile parts imported into Japan has exceeded the value of the automobiles imported, the excess being relatively much greater in 1920 than it was in 1919. This is explained by the fact that approximately 60 per cent of the motor vehicles imported into Japan are brought here as unassembled parts of cars and not as complete automobiles, a practice which is the result of a discrimination in the tariff in favor of automobile parts, together with the saving in freight charges that can be made by the closer packing. As a rule the chassis and other smaller parts are imported without the body, which is built in Japan.

## Building Bodies in Japan

As a result of the discrimination in the tariff laws of Japan against complete automobiles there has developed a considerable industry in the manufacture of automobile bodies. Almost every dealer in automobiles in Tokio, where this industry has shown the most rapid development, has facilities for building automobile bodies to order and it is estimated that from 150 to 250 automobile bodies can be manufactured in Tokio each month. Many purchasers prefer to have the bodies for their own automobiles built in Japan, because it is possible to manufacture here a body that will accommodate seven Japanese persons, besides the driver, and mount it upon the chassis of a small car, thus effecting a considerable economy.

Automobile bodies constructed in Japan are usually made of wood. A small percentage of them are built of sheet metal, but as there are no dies for pressing sheet-metal bodies, they are made by hand, and the scarcity of skilled sheet-metal workers and the higher wages paid them limits the construction of this type of body.

It has been estimated that there are no more than 9000 automobiles in Japan, of which about 70 per cent are of American manufacture.

There can be no doubt of the popularity of the small car in Japan. Its initial cost is more nearly within reach of the average income and its upkeep is less expensive. Furthermore, a small car can be handled with greater ease and speed on the narrow roads and city streets than can a car with a long wheelbase and heavy body. The high price of gasoline and motor oil and the heavy prefectural and municipal taxes on high-powered cars are also contributing factors toward the desire for low-priced machines.

The outlook for the sale of automobiles in Japan during the present year is generally considered unfavorable. The business always reflects the condition of trade in other lines and the present business depression shows little sign of improvement in the near future. There are on the docks of Yokohama a large number of automobiles, imported last year, which have not been claimed by their importers because of financial circumstances and many importing firms have large stocks of machines which they have held over from last year due to lack of demand.

## Selling Suggestions

An American automobile dealer of considerable experience in Japan suggests the following precautions, which it would be well for American automobile manufacturers to observe in preparing their products for this market.

Care should be taken in packing automobiles intended for export to this country. Too frequently they arrive in a damaged condition as a result of poor or insufficient packing. The dissatisfaction which this causes the importer is not helpful to American trade.

All steel parts of automobiles, as well as of other machinery, should be well greased before packing for shipment to Japan. This should include the interiors of the cylinders of motors. It is a common occurrence for a shipment of imported goods to remain upon the wharves in the customs compound of Yokohama for six weeks or more after being unloaded from the ship on which it arrived, because of delay in getting the goods passed through the customs. During this time the goods are often fully exposed to the weather, and this is particularly likely to happen if they are packed in large cases. The salt, humid air of the water front causes exposed iron or steel to rust very rapidly unless it is well protected by a thick coating of grease.

The fenders of automobiles intended for the Japanese trade should be given an exceptionally heavy coating of paint to keep them from rusting when used in cities and towns along the Japanese coast, where the air seems to be particularly destructive to them and gives the average fender a rusty and unsightly appearance in a comparatively short time.

\*American consul at Yokohama.

# A More Definite Statement of the Highway Research Work

It is an accepted theory that highways and their use are one problem and that this form of transportation is vital to the welfare and prosperity of the nation. Today it is an undeveloped subject. This committee is seeking fundamental information.

**A**T the recent conference of educators and industrial leaders called by the Highway and Highway Transport Education Committee, Prof. W. K. Hatt, director of the Highway Research Committee of the Division of Engineering, National Research Council, read a more definite statement of the work planned by his committee than has heretofore been made public. This report was referred to in the recently printed account of that meeting. The research work undertaken by this committee dovetails completely with the forward plans of the Education Committee, as the research must develop the information necessary for the proper education of the highway and highway transport engineer of the future.

The outline of the work undertaken by Prof. Hatt and his associates is still subject to change. The tentative outline presented at the meeting referred to follows. The committee invites suggestions.

By W. K. Hatt

**I**NDIVIDUALS in industry who have endeavored to state the problem in approximate statistics tell us that there are 10 billions of dollars invested in self propelled vehicles, and that the turnover is three billions annually. That there are ten passenger vehicles to one freight vehicle, and that the problems of speed and safety are most important. That the annual expenditure for operation of vehicles is twelve times the annual expenditure on the roads; therefore the field of research on cost of vehicle operation arising from the road surface and from the vehicle itself, must be kept in the foreground. That transportation by self propelled vehicles is the most expensive of all commercial forms; it will increase. Everyone pays for efficiency.

For the purpose of a coordinated and comprehensive program of Highway Research, the writer has been endeavoring to bring into the picture all the elements of the situation in Highway Transport: Engineering, including vehicle and road; Economics of Transportation; Administration; Finance. Some comprehensive and logical assemblage will be helpful.

It appears that there are many dimly seen figures which should be advanced from the background; there is much that is unknown. We may ask a few questions which cannot be completely answered.

## Fundamental Questions in Highway Transport

### *The Transport Unit*

- (1) What is the economical highway track unit for each of the several situations, e.g., intercity, farm to market?  
What is the cost of transport arising from vehicle and from road?
- (2) What is the relation of this economical unit to other systems of transport, e.g., electric and steam, in a unified system?

- (3) To what extent, as a matter of public policy, should any transport unit be indirectly subsidized?
- (4) What traffic regulations should be imposed on such economical unit over other types of road?  
What fees should be charged for service rendered to vehicle by the road?
- (5) What should be the proportion of the total traffic supplied by such economical unit to justify a special design of road for such unit?
- (6) What prediction can be made of future changes in general traffic and what is the influence of these on the economics of the present situation?
- (7) How should passenger traffic over the highway be evaluated?

### *The Road*

- (1) What type of road paving should be selected for a specified transport unit?
- (2) If the road cannot be economically fitted to the truck transport unit, can the latter be modified in design to fit the road?
- (3) How should the design of the road and paving be modified to meet changing conditions of subgrade, climate, etc.? How shall sub-soils be improved?
- (4) What sum of money is the locating engineer justified in spending to avoid increase in distance, curvature, rise and fall, maximum grade, maximum curve?
- (5) What system of maintenance and organization is best fitted for types of roads, differing in traffic, in materials, and in climate?
- (6) What is capacity of a road of given width for type of vehicle as expressed in vehicles per hour, ton-miles per year, etc.? What is the appropriate unit for expressing traffic for various purposes?
- (7) (In construction many questions arise in selection, production and economical use of materials, standardization and regulation.)
- (8) How can the volumetric changes in roads be overcome?
- (9) What is the economical life of various types of roads—that is, when maintenance charges exceed earning value?

### *Administration*

- (1) What should be the policy in control of truck and bus transportation systems, terminals, routing, etc.?
- (2) What police regulations should control use of roads?
- (3) What is the best administrative and executive organization for administration and operation of roads?
- (4) What principles should govern the selection of a system of roads in its various parts, as influenced by inter-state, intra-state, county, local traffic, etc.?

### *Financing*

- (1) What should be method of financing construction and maintenance of roads? What portions of cost from long term bonds, and what from current funds? What form of bonds should be issued and how create a market for them?
- (2) What should be the relation between life of bonds and economical life of road?
- (3) To what extent do social betterment, military use, i.e., social value, and other imponderables enter into highway policy?
- (4) What should be the distribution of costs as between Federal, State, county, township, property benefited, the user and other units?
- (5) How shall the future maintenance charges on completed road systems be met? Shall the user pay all of these?
- (6) How shall safety be ensured on the roads?

Answers to these questions cannot be made without data that are at present unavailable.

Research is necessary, and a mobilization of the efforts, of research agencies in a comprehensive program. The Highway Research Committee of the Division of Engineering of the National Research Council has undertaken the coordination of such research. The National Research Council will not engage in research directly.

The chart reproduced herewith is devised to indicate the field of research as divided into subfields in which research should be developed, and from which data should come to enable answers to be made to these questions among others.

Some of the studies that should be made are as follows:

- (1) To develop a traffic census blank. Here a traffic classification must be made, the purpose of the census determined, and the various forms and instructions standardized.
- (2) *In order to determine the cost of transport* a statistical table must be made that notes all of the elements of cost; sometimes only a few of these are reported.
- (3) To study the operating costs of elements entering into location of highways, such as distance, grade, curvature.
- (4) To study loads on roads as produced by the vehicle.
- (5) To study design of vehicles with a view to lessening their effects on the road.
- (6) To study supporting power and improvement of subgrades and the relations to design of paving.
- (7) To study resistance of concrete slabs to alternate stresses and to surface loads.

- (8) To study proportioning and use of bituminous materials.
- (9) To study bonding of brick surfaces.
- (10) To study volume changes and the means of meeting them.
- (11) To study operations of concrete mixers.
- (12) To study the organization and economics of construction plants.
- (13) To study sand-clay, top-soil and gravel roads.
- (14) To study cellular and other new types of paving.

There is apparently a widespread activity in highway research throughout the United States on the part of the Bureau of Roads, the U. S. Army, the State Highway Commissions, the universities and of industrial organizations and an earnest desire to put highway construction on a scientific basis.

The economical features are under critical examination by such organizations as the National Chamber of Commerce.

We should be able to express quantitatively the results of a standardized economic survey of a road project, just as in the case of a water-power project for instance, except for those imponderables, which, like social betterment and public policy, influence the conclusions so profoundly.

It is not too much to say that the situation is critical and that the sooner those interested come to a basis of fact the more assurance we will have that the public will not interrupt progress in providing for highway transport because of a general feeling of insecurity.

# The FORUM

## Truck and Trailer Relations

Editor, AUTOMOTIVE INDUSTRIES:

I have just read with great interest Mr. H. W. Perry's article on "The Trailer's Place in Transportation Merchandising," which appeared in the July 21 and 28 issues of AUTOMOTIVE INDUSTRIES.

Since Mr. Perry has mentioned the apparent previous antagonism of truck manufacturers toward the use of trailers, but, at the same time, has not presented the possible reasons for this attitude toward trailer use, I believe that a brief outline of some of the reasons for this position may be of value, particularly since I have, in many cases, recommended against trailer installations where they were not adaptable.

Up until about two years ago motor trucks in general were not designed for use with trailers. Where it was desired to handle such equipment it was necessary to alter the standard construction by changing the gear ratios, wheelbase, wheel diameter, etc., in order that a satisfactory unit could be secured. Since that time the demand for motor truck ability to negotiate severe road conditions and steep gradients has greatly increased, so that the standard modern motor truck is far more adaptable to use with trailers than previous designs. This increased ability, basically provided for another purpose (that of better general performance), has made most trucks now capable of satisfactorily pulling trailers—at least where road conditions are good and other operating requirements normal. However, it does not mean that trailers are always to be recommended.

Many trailer installations have been unsuccessful due to lack of understanding of the vital conditions so essential to satisfactory performance. These conditions include a knowledge of the tractive ability of the truck and the exact road surface conditions over which the installation is to be driven. In fact, the writer knows of a recent case where trailers have been abandoned and the trucks changed back to standard, due to a previous lack of knowledge of conditions involved in operating with trailers. Such a condition would not have resulted if an unbiased or comprehensive study of the conditions had been made by the trailer maker or his salesman.

It is indeed true that the trailer has its definite field of operation, just as has the motor truck, and the growing feeling of co-operation between truck manufacturers and trailer makers is as it should be. In fact, a closer co-operation will undoubtedly result in benefit to both parties.

In conclusion, I would like to mention the following points, which must be considered before recommending trailer equipment:

First: The trailer salesman must learn and admit the limitations of trailer equipment, and must thoroughly understand those installations where this equipment can be satisfactorily used. An installation which proves unsatisfactory not only reflects against the trailer maker, but the truck maker as well, and often causes dissatisfaction which requires great effort to overcome.

Second: A thorough study of operating conditions, including road, load, grades, etc., must be made before

recommending trailers. This is done by the truck maker, or his salesman, before determining the type or size of truck, and applies as well to the use of trailer equipment. A thorough understanding of the engineering principles involved relative to drawbar pull and performance ability must be had. I have seen many trailers discarded due to lack of appreciation of the engineering requirements.

Third: The purchaser of the truck and trailer must be properly instructed as to their use and must understand that if the conditions of operation are altered, the ability of the installation to perform satisfactorily may change. It seems that there has been a greater desire to make a sale on the part of the truck as well as the trailer maker than should be the case, particularly since it often is evident that the proper sized units have not been installed.

Fourth: Many statements made by trailer makers are misleading, and in some cases really reflect upon the truck maker. For instance, to quote from Mr. Perry's article: "The attachment of a pintle hitch hook as standard equipment on the rear of the truck indicates that that particular make of truck has drawbar pull and that the makers are selling transportation as well as motor trucks." The converse of this statement would be that a truck which did not have a pintle hitch hook could not well be used with trailers. The ability to haul trailers, as mentioned before, is based upon definitely understood values of weight, gear ratios, etc., and whether or not a pintle hook is mounted, the performance ability is in no way changed.

I believe that a more thorough co-operation between manufacturers of both types of equipment will result in discontinuing many similar misleading statements, and that the trailer makers, and particularly their salesmen, will enter their field of operation with a full understanding of all of the principles involved. The trailer has its legitimate field, and as a result I see no reason why it should attempt to encroach upon the field where motor trucks without trailers can be used, any more than either the truck or trailer can be expected to solve all transportation problems.

E. B. NEIL,  
Mechanical Engineer, Sales Engineering Division, The  
Pierce-Arrow Motor Car Company.

## The Life of Storage Batteries

Editor, AUTOMOTIVE INDUSTRIES:

We thoroughly approve of your recent articles and editorial dealing with the policy of certain car manufacturers of installing storage batteries of inadequate capacity. Our own experience of the past eight years thoroughly corroborates your conclusions.

We have had several cars which were equipped with a certain make of battery, and in no case have we been able to obtain one year of service without expensive repairs. On the other hand, our experience with another make of battery has been extremely satisfactory. We have had cars for over three years which were equipped with the latter battery which involved no expense whatever. We know of several Cadillacs purchased in 1915 or 1916 which still carry the original battery.

Our own experience is perhaps slightly better than the average since, as chemical engineers, we realize the necessity of giving a battery appropriate care. At any rate, the failure of certain batteries on our cars has never been charged by the local branch of this maker to be due to anything but natural wear. These people have told us on several occasions that one year is the maximum which anyone should expect from a battery.

We think the car manufacturers should realize that these are times of fiercest competition, and that the public, while slow to crystallize its judgments, is firm in conclusions when reached and that a reputation for equipping with a poor storage battery may readily create serious sales resistance.

E. L. CONWELL, President,

## Performance of Air-Cooled Aircraft Engines

Editor, AUTOMOTIVE INDUSTRIES:

Colonel Vincent's assumption that I referred to the RAF-4-A 12-cylinder Vee air-cooled engine in my remarks regarding air-cooled Vee engines is incorrect.

My remarks referred to the RAF-4-D and 4-E 12-cylinder Vee engines, these being RAF-4-A engines fitted

with overhead valve aluminum cylinders and having a very different performance from that of the RAF-4-A engine quoted by Colonel Vincent.

The performance of the RAF-4-D engine was as follows:

220-b.h.p. at 2000 r.p.m.  
Fuel consumption .52 lbs.  
Weight complete with cowling 650 lbs.  
Bore—100 mm. (3.94 in.).  
Stroke—140 mm. (5.51 in.)

At the time of design (1916-1917) this performance did not compare very unfavorably with the best water-cooled engines, especially when considering that the balance of the engine apart from the cylinders was practically all of pre-war design.

Colonel Vincent's opinion that the radial form was adopted for cooling reasons, if based on the performance of such engines of the RAF-4-A and similar types, would no doubt be correct, had air-cooled cylinder design remained stagnant since 1914.

When criticising the air-cooled Vee engine it is well to consider the wonderful performances put up by the early Renault engines, the latter on account of its pioneer work is really the father of modern air-cooled aircraft engine.

S. D. HERON, Power Plant Section,  
McCook Field.

## U. S. Leads in New Zealand Imports

DURING the first four months of 1921 the Islands of New Zealand imported a grand total of 2891 motor vehicles, made up of passenger cars and chassis, motor trucks and chassis, and electric passenger cars and electric trucks. Of this total, the U. S. A. and Canada furnished the major amount, the U. S. A. leading with a total of 1258, followed by Canada 1111, and the United Kingdom 361. France, Italy, Belgium and Australia supplied the remainder. The following tabulation shows the classification and origin:

NEW ZEALAND IMPORTS, JANUARY, FEBRUARY, MARCH, APRIL, 1921

	U. S. A.	United Kingdom	Canada	France	Italy	Belgium	Australia
Passenger cars	1,082	207	779	18	24	13	3
Passenger car chassis	27	6	13	44	13	4	..
Motor trucks	120	113	99	3	..	..	..
Motor truck chassis	29	35	220	33	..	..	..
Total	1,258	361	1,111	98	37	17	3

Ford importations come from the Canadian factory which accounts for the total of 1111 cars and chassis as compared with a total of 1258 from the U. S. A.

In the importation of motor trucks and chassis Canada leads with 319, compared with 149 from the U. S. A. and 148 from the United Kingdom. Here again unquestionably the Ford figures are largely responsible for the Canadian total.

During the 4 months there were only six electrically-driven motor vehicles imported, these all coming from the U. S. A. in the form of motor truck chassis.

Total figures on imports of cars and trucks into New Zealand during 1919 and 1920 were recently published by The Radiator, the organ of the New Zealand dealers association, known as The Motor Garage Proprietors' and Cycle Traders' Association of New Zealand, Inc. These totals are:

	1919	1920
Passenger cars	5,270	10,541
Trucks	804	1,431
Tires (pounds sterling)	860,048	1,803,959
Spares and parts (pounds sterling)	118,724	240,997

An analysis of the imports during the calendar year of 1920 shows a total of 7447 cars and trucks from the U. S. A. Canada was second with 3852 and the United Kingdom third with 615. The following tabulation shows the origin of imports:

	Passenger Cars	Passenger Chassis	Trucks	Truck Chassis	Electric Passenger Cars	Trucks, Electric	Total
U. S. A.	6,977	89	204	163	1	13	7,447
Canada	2,850	178	258	566	..	..	3,852
United Kingdom	352	21	168	68	..	6	615
France	20	4	..	..	..	..	24
Italy	11	33	1	4	..	..	49
Australia	6	..	..	..	..	..	6
Total	10,216	325	631	801	1	19	11,993

In the importation of tires the greatest volume came from U. S. A. with Australia second, France third, United Kingdom fourth, Canada fifth and Italy sixth. The following figures in pounds sterling show the volume of business for tires and tubes and also for parts for vehicles:

	Tires and Tubes	Parts and Materials
U. S. A.	131,143	48,079
Australia	79,484	1,764
France	51,748	435
United Kingdom	43,189	20,503
Canada	37,835	30,359
Italy	36,766	806
Belgium	437	..

When the imports of tires and parts for the calendar year of 1920 are considered the following figures show the U. S. A. to lead in tires, followed by Australia, Italy, Canada, United Kingdom and France. The figures are:

	Tires and Tubes	Parts and Materials
U. S. A.	709,591	147,751
Australia	321,382	6,872
Italy	226,963	17
Canada	220,362	46,585
United Kingdom	168,930	35,263
France	154,137	388
Belgium	1,730	120
Japan	864	1

# Human Factors Largely Responsible for Waste in Metal Trades

A recent report indicates that waste in the metal trades runs to one thousand million dollars annually. Much of this is due to lack of understanding of the relation which human beings bear to efficiency of operation. The report is summarized and discussed here by Mr. Tipper.

By Harry Tipper

**T**HE report of the Committee on Elimination of Waste in Industry appointed by the American Engineering Council has been issued in respect to the metal trades and this report has been noted by the newspapers and other general publications.

The report itself should be of interest to the automotive manufacturer, because it covers a line of industry similar to that in which he is engaged and in a large measure relates to products or material which he must buy in considerable quantities during the year. Any waste to be found in the general metal trades affects the cost of the automotive manufacturer in a number of directions. It is possible that the manufacturer of automotive apparatus might find interesting material for an analysis of his own plant from the suggestions of the report.

It is evident from this report that the causes of the waste are in a large measure human.

The waste itself is reported to run to one thousand million dollars a year in this industry. The figure is a very impressive one, but in view of the size of the metal trades industry, it is not likely to be overestimated. If all the waste could be computed, it is probable that it would reach a total much larger than the one indicated by the committee and that it would cover items not considered by the committee.

The executives in production will not be inclined to agree with the statement on paragraph four of the report:

**"It is estimated that at present about 80 per cent of the responsibility for waste or non-production rests with the management—that is, with the managers and executives in the plant."**

There is no way of checking this percentage so that its accuracy can be determined. Except for the percentage itself, the statement is correct in essence, and until the executives and managers of industry fully understand the extent of their responsibility, a large part of the waste will continue to go on.

The centralized systems of industry usually operating to-day do not encourage the continual alert analysis of the operations and human possibilities, so that the value of the present methods can be determined. The precedents, rules and regulations of the present systems have become so much a part of the attitude of the younger executives that their judgment is almost limited to these and does not exercise itself outside of the rules or in questioning the systems themselves. The older executives, who received their training when industry was much younger and very different in its methods, are usual-

ly so far away from the present system in its detailed operation as to be unequipped to analyze it and to deal with its inefficiencies.

The replies received from the manufacturers in the thirty-two plants visited indicated this lack of understanding on the part of the managing executives and the way in which the elements of the systems themselves are neglected.

These statements are quoted so that their diversity and ineffectuality may be properly noted.

Being asked their (the managing executives) opinion as to the main cause of waste or inefficiency, their answers were as follows:

In eight plants the answer referred particularly to present business conditions and was to the effect that "the most important cause is the uneven volume of business or the fluctuation in the demand for the product; lack of enough business to keep going at normal capacity."

In four plants the cause given concerned the railroad situation and the functioning of the Railroad Adjustment Board.

In three plants the cause given was "lack of standardization of design of products."

In two plants the cause given was "labor turnover and strikes," one executive saying that these had been caused by wartime conditions.

In four plants the cause given was "lack of planning"—the exact words being "lack of proper planning and routing;" one "lack of correct planning and material control;" one "unscientific planning and management;" and one "lack of efficient planning and management methods."

In six plants the cause given was "lack of co-operation between management and labor."

Other causes given in various plants were as follows: "Lack of intensive study of methods;" "cost control systems needed;" "daily cost reports needed;" "lack of scientific management applied to all phases of the business;" "inefficiency of labor and excessive overhead."

In other plants special causes in the machine-tool business were given as follows:

"The failure of machine-tool builders to supply what the public wants."

"Most of the metal trades shops are very small and require personal handling by the manager of such important problems as are handled by our system of production control."

Insufficient capital to develop sales and to improve facilities.

Purchasing in small quantities, by the small plants, which places them at a disadvantage as to favorable prices and as to transportation and handling expense.

All the causes noted in the statements of the managing executives of the plants are subsidiary causes arising

ing out of the failure in other directions and not fundamental or primary causes in themselves.

A little thought will show that these causes are due—all of them—to a lack of analysis, particularly the absence of the analysis of the human side and the relation which labor bears to the efficiency of the operation.

This is the case not only with the labor in the shop, but with the supervisors and departmental executives who require a greater degree of understanding and who should be chosen with greater analytical care.

Lack of standardization, labor turnover, lack of proper planning, lack of intensive study, excessive overhead, failure to supply what the market requires, insufficient capital, and so forth, are all questions of management.

It is the distinct and definite responsibility of management to see that proper systems are adopted and that these systems are economical and not wasteful. It is the responsibility of management to see that there is co-operation between the supervisor and the worker. There is no escape in any of the cases from the responsibility imposed upon the manager to know what systems, what measures and what studies are required in his own shop, for his own purposes and to see that these are planned and adopted.

There is no escape from the responsibility placed upon the manager to understand those who work in the shop, to study them so that he will thoroughly understand them, to work with them, and to see that the matter is so arranged that there is an incentive for the worker to put forth his full power. Neither is there any escape from the responsibility resting upon the management to see that each man is given the amount of responsibility in harmony with his operations and that the system is sufficiently flexible

to encourage him to exercise his judgment in meeting this responsibility.

Of course, this responsibility of the management is only beginning to be recognized. A few years ago the only responsibility understood or accepted by management was the responsibility of making a profit. The responsibility of making a profit does not lead to an intensive analysis of the probable wastes, unless those wastes interfere with the profit itself. In an era of extensive business such as we have passed through, the prices which can be secured for the products will permit the profit, even with a large amount of waste entering into the costs of their production.

The whole of the many pages of this report can be summarized in the statement that the wastes are wastes of human capacity and energy, of human analysis and understanding arising out of the ignorance of human reactions and the elements governing human efficiency.

No better illustration could be offered of the necessity for the study of humanity in industry than the statement of a billion dollar waste, of which at least eight hundred millions are admitted to be the waste of human ignorance in regard to human necessities.

Without regard to the accuracy of the report in many respects, the report itself should give plenty of food for thought to the average manufacturer.

In the near future the manufacturer will be required to produce with much less waste in order to meet the competitive conditions and still retain the profit he has been accustomed to make. This reduction in the cost of production cannot be met merely by changing the rates of wages, it must be met very largely by increasing the efficiency of production.

## Truck Wheel Standardization in Germany

**I**N Der Motorwagen the suggestion to standardize cast steel motor truck wheels is made by Engineer Kienzle, who is evidently a member of the Standards Committee of the German Association of Automobile Manufacturers. Outside diameters and widths of tires, as well as inside diameters of rims, have been standardized already. It is estimated that complete standardization would result in a reduction of 50 per cent in the cost of production. Two general designs of front wheel hub are illustrated, both adapted to the use of either ball bearings or floating bushes. In the first the hub has a smooth bore and receives a sleeve, whether plain or ball bearings are used. In the second the outer races of the ball bearings are mounted directly in the hub, and as the outboard bearing is of much smaller diameter than the inner bearing, the wheel hub must be bored out to two different diameters. The elimination of the sleeve, of course, saves the cost of its manufacture, but it is difficult to turn ball bearing seats directly in the wheel (which is handled in a vertical turret lathe) with the accuracy required for the purpose. The sleeve would be bored in a precision lathe in which the required degree of accuracy is easily attained. Another advantage of the sleeve construction is that when wheels are interchanged the ball bearings need not be disturbed, and as the replacement usually takes place outside the factory, it is believed that this would obviate much trouble, as incorrect replacement of the ball bearings or the admission of grit would lead to their rapid destruction.

If plain bearings are used the cost of construction of the two designs would be about the same, as the slight extra cost of the sleeve with two diameters would be bal-

anced by the reduction of materials cost for the whole wheel and the saving on the smaller hub cap thread.

It is also stated in the article that steel foundries figure that wheels with cruciform spokes can be manufactured at about 75 per cent of the cost of wheels with hollow spokes, partly owing to reduced wastage, which in the case of hollow-spoked wheels is mainly due to incorrect placing of the cores. The core work in itself is quite an item of expense.

## The Aircraft Year Book

**T**HE third edition of the Aircraft Year Book is being distributed. This volume continues the same effort put forth in the previous Aircraft Year Books—a presentation of the air transportation development of the previous year. These volumes are a commendable effort in preserving a continuous history of the development of this new phase of transportation. The present volume is technical in only a slight degree, but chiefly presents a story of practical development. The text includes a list of the commercial companies operating in 1920, with a report of operation mileage, which report has been printed in AUTOMOTIVE INDUSTRIES. Chapters are devoted to the operation of the Air Mail Service, Aerial Forest Patrol, the Marine Uses of Aircraft, Aerial Photography, News Gathering, the Need for Federal Control, Air Ports, Military Uses and similar live topics. The appendix gives many facts concerning the industry. In the technical section the design of present aircraft is traced from the Wright Bros. machine in a series of drawings. The volume is published by Small, Maynard & Co.

## Petroleum, Iron and Coal

HOW important a factor petroleum has become in the world's commerce during the past several years is well brought out by some statistics contained in a paper on The Effect of the War on Mineral Supplies, presented at a recent meeting of the (British) Institution of Civil Engineers. It is shown that whereas most lines of mineral production fell off heavily in the course of the war, the production of petroleum increased more than 75 per cent. The output of coal dropped from 1,320,000,000 tons in 1913 to 1,130,000,000 tons in 1919, and the output of iron ore from 175,000,000 tons in 1913 to 145,000,000 tons in 1917, but the output of petroleum increased from 55,000,000 tons in 1913 to 98,000,000 tons in 1920.

The decrease in the production of coal and iron ore was certainly not due to any lack in demand for these products; the enormous increase in the price of coal, particularly in European countries, indicates a very heavy demand, and the sole reason for the drop in production was the lack of sufficient labor. Petro-

leum producers had to meet this same difficulty of scarcity of labor, but they found the labor necessary to nearly double their output, while other industries devoted to prime necessities fell back. The conclusion to be drawn is that during the world war petroleum was a more important factor than either coal or iron; or, more precisely, that an increase in the output of petroleum was more urgent than an increase in the production of the other two basic materials.

## "New and Useful"

THE patent law of the United States provides that, in order that a patent may be secured on an application, the device on which the application is based must be new and useful. Undoubtedly the patent laws of other countries make similar requirements, though the efforts made to look up records and determine novelty vary to a considerable extent. Up to not so very long ago the United States and Germany were the only countries whose patent departments made a search for possible anticipations. The search in any case is limited, and the Government does not guarantee the validity of the patent which it grants; if it is contested it remains for the courts to decide the matter.

Recently there has been some discussion in England as to the extent of the search made by the British patent office to determine the novelty of applications, and it has been brought out that this is limited to the British patent records for fifty years back. That under these circumstances many applications are allowed that would seem unpatentable is obvious. We were reminded of this discussion on seeing in a British engineering paper an abstract of a patent recently granted to the Daimler Motor Co. and A. E. Berriman on Improvements in Electric Lighting Systems for Motor Vehicles. A switch in the lighting circuit connects a resistance in one of the battery leads for the purpose of dimming the lights momentarily, thereby avoiding danger and discomfort to the drivers of oncoming vehicles.

We had thought that the use of a resistance in series for the purpose of dimming lights was known to everybody having to do with electrical work, as it is common practice in the electric lighting of motor vehicles in this country. It is easily believable that no patent was issued on the system in Great Britain during the fifty years preceding this application. Every electrician is familiar with the effect of including a resistance coil in a constant potential lighting circuit, and the thing is so obvious that hardly anyone would have the temerity of applying for a patent on it.

## Concerning Detonation

IT seems to be agreed that detonation with its accompanying knock which occurs during the combustion of fuel in an engine cylinder is a factor of prime importance in relation to the value of internal combustion engine fuels. The cause of detonation is thought by some to be due to an extremely rapid combustion or liberation of energy. In any case the

accompanying pressure rise is known to be very great and exceedingly rapid. The results are certainly injurious to the engine and are most unpleasant so far as the engine operator is concerned.

There appears to be but little doubt that if the effects of detonation could be avoided, higher compression or expansion ratios could be employed and higher thermal efficiencies obtained. This fact alone is sufficient reason for strenuous efforts to overcome or control detonation, but there is considerable doubt as to how this can be accomplished. The use of certain diluents or dopes in the fuel appear to be promising, but it remains to be seen how generally they will be employed, and many question whether they will after all prove to be an answer to the problem. It is well, however, that their utility is being investigated, for the fuel problem is so important that it is well to prosecute every possible line of attack upon it which appears at all promising.

One so-called fuel "dope" tried recently at the Bureau of Standards was found to overcome the knock when used in a fairly large proportion, about 10 per cent, but the maximum power output of the engine was also reduced. Precisely the same result was attained, however, by making provision whereby the spark could be retarded further than is possible with most retard mechanisms. Dopes are supposed to slow down the rate of burning of the fuel and a late spark is thought to accomplish the same result. This raises the question as to whether the relation of spark advance to the detonation phenomena has been adequately considered and investigated. There is, of course, no point in using doped fuel if the same effect upon performance can be obtained by simply changing the ignition timing. Our present knowledge is too limited to draw any general conclusions in this regard, but it is a matter worthy of further careful research work.

## Confidence Cuts Expenses

THE chief executive of a large unit parts firm said the other day: "If our customers would so far take us into their confidence as to tell us with some degree of frankness what are their plans for the next three months, we would be able to save thousands of dollars in production expense—and a fair share of the saving would accrue to the automobile factories in the long run." The loss incident to the cancelation of a contract to purchase parts must of necessity be added in the end to the purchase price. Hence the purchaser ultimately stands the loss.

While it is doubtless true that many manufacturers are somewhat hazy as regards their plans for the next three months, every firm has, or should have, more or less accurate ideas as to the immediate future. From every part of the various industries contributing to the automobile industry has come the complaint that the parts maker is not sufficiently taken into the confidence of the manufacturer as regards future plans. It is not possible in every case, of course, to consult freely with supply sources, yet it is probable that a greater measure of co-operation would greatly benefit both parties.

Modern industrial organization is composed of

units so closely inter-dependent that only through sincere co-operation and a recognition of a moral as well as a legal obligation in doing business can permanent progress be made. The conviction is growing that to give more is to get more. That this is a practical business doctrine is being evidenced more frequently in all industrial relationships, between employer and employee, between manufacturer and consumer, and between manufacturer and manufacturer.

## Nomenclature for Isolated Electric Plants

THERE has been considerable discussion concerning the best nomenclature for the electric units formerly called farm lights. Such lights are now being used extensively in motion picture theaters, business plants, and other establishments, however, so that there appears to be a need for a more inclusive name.

Some time ago AUTOMOTIVE INDUSTRIES dropped the name farm light plants. It has used instead the term "isolated electric plant." Believing that it would be highly desirable for the industry represented in the manufacture of these units to agree as nearly as possible on a proper designation of these plants, AUTOMOTIVE INDUSTRIES recently sent a questionnaire on the subject to the chief manufacturers. The questionnaire asked these questions:

1. What is your idea of the proper designation?
2. In your opinion, whose task should it be to establish a nomenclature for this rapidly developing industry?

The replies received to these queries indicate that there is a rather general agreement on the isolated electric plant terminology. Several manufacturers, while they do not use this term exclusively at present, believe it to be the best available. The National Gas Engine and Farm Power Association is frequently mentioned as the organization whose task it should be to establish the nomenclature for this industry. One maker suggested the Society of Automotive Engineers in this connection.

Only one reply definitely opposed the term isolated electric plant, on the ground that the term isolated does not have a pleasing sound to the prospective purchaser. This company writes, "In our advertising we have featured these plants as electric light and power plants, leaving out the word farm entirely. It is possible that some better designation than has yet been suggested can be thought of."

There were numerous suggestions that the business papers should be active in attempting to establish a standard nomenclature. It is evident from the replies that considerable discussion along this line has already occurred in the Gas Engine and Farm Power Association. One reply states that "each time the matter is brought up in a meeting of the manufacturers of these plants there are as many suggestions as to the proper designation as there are members present."

A survey of all the replies, however, indicate a very general agreement as to the advisability of using the term isolated electric plant.

## Industry Suffering from Short Credit, Avers W. C. Durant

Thinks Much of Present Distress  
Due to Extortionate Interest  
—Flays Bankers

NEW YORK, Aug. 9—Recovery of the automotive industry, which is suffering from the same causes as all other industries, will be surprisingly rapid and will take the lead in industrial activity, is the opinion of W. C. Durant. The automotive industry is, and will continue to be, an essential factor in the development of civilization, he contends. It has gone through its period of reconstruction, has organized its methods to meet the new order of things and is better prepared to-day for a running start than almost any other branch of industry.

The solution of the gravest of the problems which confront the business men of the country rests upon adequate credit, Durant asserts. In this connection he says:

"When cheaper money is available for business men who need it, when credit is extended in generous measure to business men who are entitled to it, when Government securities have been put on a 100% basis, we will hear less about 'frozen credits,' courage will be restored and the usual American action, which we all so much admire, in place of indifference and apathy, will be in evidence and we will quickly get back to normalcy."

The views of Durant, long a real captain of industry, are contained in a statement prepared by him for the current issue of Commerce and Finance. In this statement he arraigns mercilessly the attitude of big bankers and charges them with exploiting the needs of legitimate business for selfish purposes. In this connection he says:

"I contend that much of our present distress is due to extortionate interest rates and restricted credits. In this financial crisis the bankers have not met the situation and are largely responsible for the chaotic condition now existing."

"Never in the history of this country was there greater need for low interest rates and more elastic credits."

"Instead of helping to relieve the situation and restore order, the bankers and those in control of the money supply and credits have been taking advantage of a situation. For months, call money rates have been outrageously high, with time money almost impossible at any rate—and this condition existing with our natural and accumulated wealth, with nearly one-half the gold of the world in our possession and with a great Federal Reserve Bank created for the purpose of doing a real service to commerce and industry in an emergency."

"If money and credit are available only for certain preferred purposes and at certain rates, business is bound to suffer. The Sherman Law and Clayton Act

are intended to prevent monopoly and control, but no good plan has yet been worked out which gives to a perfectly solvent concern the ability to obtain a line of credit to which it is entitled at terms that are just and legal.

"At a time when business in every industry and commercial line is suffering and business men in all lines are carrying tremendous burdens, the bankers are exacting the highest rates ever known and forcing liquidation beyond all reason. Word went forth some time ago: 'Liquidate and pay.' And liquidation has been going on at a fearful rate and at a terrific sacrifice."

"The Federal Reserve Bank was created for the purpose of meeting emergencies. How did it meet this present emergency? By establishing unattractive and prohibitive rates, making last year the enormous profit of 200%. By advocating and encouraging liquidation in the face of a business and industrial crisis such as this country has never before known. Result—business paralysis, with industry, the life of our country, so weakened and enfeebled as to make recovery slow and painful."

"I recall recently having heard of many of our well established and well managed concerns in industrial pursuits reducing or passing dividends, but I have yet to hear of a single well established or well managed bank reducing or passing dividends or showing any falling off of earnings."

"And what have you to suggest? you ask. My answer: Give the business men of this country 1% call money? Let the Federal Reserve Bank establish a discount rate of 3%. Let our banks stop forcing liquidation. Let our banks extend rather than curtail credit."

"Let the big bankers of this country, who control the money situation, do the right, fair, honest, decent, unselfish thing just this once, and for their own good and safety and the benefit and safety of this country and our people, do it now."

## A. A. A. Will Seek Cheaper Insurance for Members

WASHINGTON, Aug. 9—The executive board of the American Automobile Association has decided to widen the scope of the association's activities. One of the subjects which will be taken up is that of automobile insurance. The question has been placed in the hands of a committee which has formulated plans for cheaper insurance for A.A.A. members. Retention of counsel familiar with automobile law to provide free legal advice to members will be given immediate consideration.

A new method of protecting members' cars from automobile thieves is being evolved and will be tried out in the near future in Washington.

The A.A.A. will renew at once its efforts to obtain the passage of a national reciprocity law which would mean that motorists could travel anywhere in the United States for unlimited periods with their home state license tag.

## Durant Motors Takes Over Sheridan Plant

Production of New "Durant Six"  
Will Start in Month or More  
at Muncie

NEW YORK, Aug. 9—The plant of the Sheridan Motor Car Co. at Muncie, Ind., was taken over on Aug. 1 by the Durant Motors Co. of Indiana, a \$3,000,000 corporation of which D. A. Burke is president and general manager. Only the plant itself was purchased and the new owners did not acquire the inventory which had been assembled by the General Motors Corp. for the Sheridan car.

Production of the Sheridan, which will be rechristened the Durant Six, will not begin for a month or more under the new ownership. The models are being redesigned and rebuilt at the Long Island City plant. They will retain practically nothing of the old Sheridan. The Durant engine will be used and all the principles of design embodied in the Durant Four will be included in the Six. One of the main features will be the accessibility of the various parts and another will be the strength of the chassis.

The general body lines designed by Burke will be retained except that the hood will be lengthened eight inches. When Burke designed the Sheridan he worked out ideas he long had cherished of building a luxurious car which would sell at a moderate price with many of the refinements found in those of the higher price classes. He sold this idea to Durant and the result was the establishment of the Sheridan division of General Motors. This idea will be retained by the new company but the car which will be turned out will be much more powerful than the one which was built up to Aug. 1.

The prices of the various models of the Durant Six will be: Roadster, \$1600; touring car, \$1650; coupe, \$2250, and the sedan, \$2400.

The sedan model of the Durant four now is ready for production and will sell at \$1365. The coupe will sell at the same price but a few changes are to be made in the body lines.

## Severin to Move Plant; to Employ 500 Workers

OAKLAND, CAL., Aug. 10—The Severin Motor Co. of Kansas City will move its factory from that place to Oakland, according to J. R. Elrod, local representative of the company, with offices in the Henshaw Building here. The decision to locate here was made after H. T. Severin, president of the company, had inspected sites in several Pacific Coast cities, Elrod said. The new plant will cover four acres, and the first unit, 60 x 450 feet in size will be started immediately, according to the local representative, who placed the cost of the first building at \$300,000, but admitted that the land for the plant had not yet been purchased.

## Capitalists to Get Engineers' Report Favoring Dirigibles

**Benedict Crowell Will Sign Recommendation for New York-Chicago Air Line**

WASHINGTON, Aug. 9—Marked progress has been made in the development of dirigible transportation in this country. On Friday of this week a report favoring the establishment of air lines between New York and Chicago, and ultimately between New York and San Francisco, will be submitted to a powerful group of financiers assembled in New York. The recommendations will bear the signature of Benedict Crowell, formerly Assistant Secretary of War, and Edward Shiladar, a noted consulting engineer who assisted General Goethals in building the Panama Canal. After nearly two years of intensive study in Holland, Germany, France, England and Italy, these engineers are convinced that aerial transportation by dirigibles is the safest, fastest, most profitable and economical method of travel at present, and, in addition, has infinite possibilities for development.

It is believed that when the bankers are told that the investigation discloses commercial advantages, they will decide that the plan should be put into effect immediately. It also is expected to give impetus to research by American engineers in this field of industrial activity and ultimately result in the establishment of factories in this country for the construction of dirigibles.

There are no plants of this kind in America to-day and American bankers are desirous that the country should be independent of foreign manufactures. Plans have practically been completed for undertaking this gigantic enterprise with a capitalization of \$50,000,000. Powerful industrial and financial groups are co-operating in this work. A heavy investment will be required if the aerial line is operated without governmental assistance.

### Propose "Blimp" Hangars

Proposals have been made to use navy "blimp" hangars on Long Island, St. Louis and elsewhere, but the engineers feel that it would be best to construct private terminals. It is estimated that these terminals would cost approximately \$6,000,000 each, while the first set of dirigibles would cost about \$2,000,000 each.

Negotiations have been conducted with the Schutte-Lanz Co. in Holland and with German and Italian construction firms, but the deal has not been closed. Crowell and Shiladar devoted particular attention to the patents and the engineering features. It may be possible to bring engineers from Holland and Germany to this country to build up an industry here but this is not the con-

trolling feature in the arrangements.

According to the engineers' estimates, it will be possible to use three ships about the same size or slightly larger than the R-34 which flew from England to this country. The tentative plans call for a carrying capacity of 100 passengers to cover the flying distance from New York to Chicago in ten to twelve hours, with a possible guaranteed 12-hour trip.

The Dutch and German ships are luxuriously equipped but the plans of the engineers call for the elimination of many non-essentials in upholstery and furnishings in order that the weight may be lessened and the cost of the craft reduced. A study of trans-continental, trans-Atlantic and trans-Pacific aerial routes shows that Chicago would be the logical aerial center of the world.

Further details regarding the mechanical features of the dirigibles will undoubtedly be given to the public at an early date, when the financial arrangements are actually completed. Officials of the investigating body stated that sentiment among the financial interests favors the establishment of this form of transportation and that many manufacturers of heavier-than-air machines had manifested a friendly interest.

## File Bankruptcy Suit Against Shuler Axle

LOUISVILLE, KY., Aug. 8—Alleging that certain creditors of the Shuler Axle Mfg. Co. have been preferred over them, other creditors have filed an involuntary petition in bankruptcy against the company in United States District Court. It is alleged that the company has liabilities of \$385,000 with assets of \$250,000.

The Shuler Axle Mfg. Co. is a Michigan corporation and was organized in Detroit about four years ago. It manufactures front axles for automobiles.

According to the officers of the company it was forced into bankruptcy because its assets were tied up in securities and materials which could not be liquidated. The officers of the company are: J. J. Kean, president; R. P. Noud, vice-president, and F. A. Shuler, secretary-treasurer.

## Ford Sales Show Gains in South and Mid-West

DETROIT, Aug. 10—While Ford business in all parts of the country is continuing at record heights, the company is particularly elated with improvement in the South and Mid-West, where for a long time things were at a standstill.

In an analysis of the changed situation in the South the company expresses the belief that the elimination of the one-crop plan in favor of diversified crops is responsible for the new order of things. Prosperity will be no longer dependent upon the market price for cotton or sugar or rice, Southern dealers assert to officials, but will be a permanent and welcome guest in the land.

## Creditors Ask Sale of Standard Parts

**Ask Federal Judge for Order—  
Figures Receiver Submits  
Questioned**

CLEVELAND, Aug. 9—Creditors of the Standard Parts Co. met here to-day and voted to ask Federal Judge D. C. Westenhaver to grant an order for the immediate sale of the property of the \$20,000,000 corporation which is engaged in making automobile accessories and parts. Judge Westenhaver appointed receivers for the corporation last September upon application of the stockholders.

An all day discussion preceded the action of the creditors and at times the debate grew stormy. P. A. Connelly, secretary of the company, testified that when the Standard Parts Co. was formed the capital of the corporations entering the combine was written up to the extent of \$5,156,000. Since the merger was formed, he said, it had lost \$8,094,000. He also attacked the inventory filed with the court, the figures in which were prepared by expert accountants.

Connelly said that the inventory should be reduced and he contended that the assets were in reality but \$1,000,000 in excess of debts. Attorney A. V. Cannon, who represents the receiver, Frank Scott, asserted that the inventory was correct and that the assets of the company amounted to approximately \$18,000,000. He said that after paying all debts the preferred stockholders would have left 100 per cent equity in the company.

The creditors have a plan for the sale of the property under which they would bid in the plant, form a new company and offer stock in it to the stockholders of the present corporation. Those not purchasing would lose all they had invested. The creditors would have control of the new corporation.

Judge Westenhaver took under advisement the appeal of the creditors and he did not give his opinion on the petition of the receiver for an order to pay creditors a dividend of 10 per cent on their claims.

### Court Action Put Off

Action likewise was postponed by the court of the request of the stockholders that the receiver be continued for the present. Clevelanders who have been following the corporation's affairs see a hard fight being made for control by a certain group. A majority of the stockholders profess to be satisfied with the showing of the receivers who have been making money for them in the last few months. They hold that if the corporation is dissolved and the plants are sold they stand to lose. They are fighting hard to convince the court that if the present management continues, with good fall business ahead, the company will be strengthened very materially financially.

## 7266 Workers Added to Payrolls in July

### U. S. Survey Shows 4.2 Increase in Employment in Automotive Industry

WASHINGTON, Aug. 10—Slight increase in employment in July has been reported for the automobile industry, after a survey by the special agents of the United States Employment Service. Under the classification of "Vehicles for Land Transportation," the industry is reported to have added 7266 to the payroll, representing an increase of 4.2 per cent.

#### Much Part Time Work

In Michigan the official agents found that part-time employment was prevalent, but strenuous efforts were being made to stimulate business by increased advertising, additions to the sales forces, more attention to efficiency of operation, and by reducing costs and labor turnover. In Flint it is reported that the automobile plants are active, although not working on full time. A gradual return to normalcy is expected in other automobile centers through the district. However, the analysis of returns would seem to indicate that in the majority of instances where there has been improvement in the employment situation it is primarily traceable directly or indirectly to the harvest and other seasonal agricultural activities. Secondly, and to some extent as a natural corollary, there have been material gains in railroad occupations, principally in those which have to do with repairs to rolling stock and roadbeds.

Despite an obscured outlook there is manifest a very general optimism which everywhere agrees as to the certainty of an approaching business revival and varies only in the predicted time it is destined to arrive.

Widespread unemployment and part-time continues in practically all lines, particularly in the metal and building trades and transportation circles. While certain textiles show a marked improvement, frequently reaching normal and even exceeding it, and orders for shoes are being taken, the general employment situation throughout the district has not improved.

## Net Sales of Franklin \$14,393,858 in 6 Months

SYRACUSE, Aug. 6—H. H. Franklin Manufacturing Co. in its mid-year statement to stockholders dated June 30 reports net sales for the first six months of 1921 of \$14,393,858 with a net profit of \$735,826. The net income for that period was \$786,561. Sales for the six months equalled 82 per cent of sales for the same period of 1920 and June sales of 1046 cars were the largest for that month in the history of the company.

Cash on hand June 30 was \$850,386,

compared with \$1,748,294 on Dec. 31. Sight drafts and Government bonds were \$293,853 as compared with \$986,558, accounts and notes receivable had increased to \$715,154 from \$591,202. The merchandise inventory had been cut down to \$5,990,701 from \$7,614,695. Total current assets were \$7,850,096 as compared with \$10,940,752 six months earlier.

There was a very large reduction in current liabilities for the first half of this year, the total being \$2,528,360 as compared with \$7,368,180 on Dec. 31. Bank loans of \$4,510,000 were wiped out completely. Current accounts payable and miscellaneous liabilities were \$2,528,360 as compared with \$2,858,180. The company reserved \$2,209,421 for depreciation of fixed assets.

## Milwaukee Factories Still Taking on Men

MILWAUKEE, WIS., Aug. 10—While manufacturers of motor cars and trucks, motors, frames and other parts are still adding men to payrolls, the rate of increase reached during the early part of July is not generally being exceeded, since operations now are commensurate with current demand and expectations of the call from distributors and dealers for the remainder of the summer. It is believed unlikely that any considerable enlargement of production will be necessary until the fall demand becomes apparent, for manufacturers are not inclined to make up cars for stock and keep output closely related to current orders.

The most hopeful sign of the week is the reopening of railroad locomotive and car shops in Wisconsin and elsewhere, giving employment to a great many men who have been out of work since February or March, or who have been employed half-time or less by the rotation system. As a class, railroad men were an important factor in the sale of passenger cars during the period of high wages and general employment, and it is regarded as being favorable to car sales in the coming months that conditions should take a decided change for the better in their situation. The main plant of Nash Motors Co. at Kenosha has virtually reached the 3000 mark in number of employees at work on full time. The Milwaukee plant is back at normal capacity of 1000 men. The Waukesha Motor Co. at Waukesha, Wis., is adding 200 men, giving a total of 400.

#### HAYNES TRACTOR DENIAL

INDIANAPOLIS, Aug. 10—Officials of the newly organized Haynes Tractor Co. and allied interests denied the rumor that they were contemplating taking over the Mid West Engine Co. of this city in a statement. Both Elwood Haynes and A. G. Seiberling declared the report was untrue. The new Haynes company took over the Tractor Co. of Indianapolis, and the Powell Tractor Co. of Elwood, and was incorporated at Indianapolis a couple of days ago.

## Many Tire Plants Offered Seiberling

### Former Goodyear Head May Operate Chain of Factories— Plans Developing

AKRON, Aug. 10—Although Frank Seiberling, founder and former president of the Goodyear Tire & Rubber Co., has issued through his secretary, R. C. Ellsworth, a formal denial of his rumored acquisition of the Republic Rubber Co. plant at Youngstown, his recent conferences with trustees of the Republic company and his inspection of other small rubber plants have given rise to the firm belief that Seiberling plans to stage his "comeback" in the tire industry by establishing and operating a chain of small tire plants scattered throughout the country.

#### Heads Many Companies

Seiberling virtually is in control of the Lehigh Rubber Co. of New Castle, Pa., which he purchased some time ago at receiver's sale. He is one of the controlling heads of the Star Rubber Co. of Akron. His secretary, R. C. Ellsworth, is heavily interested in the Marion Rubber Co. of Marion, Ohio, while W. E. Palmer, former Goodyear treasurer, now is trustee of the Marion company. Bargain offers for sale of the Republic plant at Youngstown are known to have been made to Seiberling.

In addition many small rubber plants throughout the country which now are in the throes of financial difficulty have been offered to Seiberling across the bargain counter. Seiberling is expected to make some formal announcement shortly relative to the scope of his renewed activity in the tire industry and the number of small plants which he expects to control and to operate.

#### In Touch with Officials

Soon after Seiberling retired from Goodyear, A. G. Partridge, former vice-president and sales manager of the Firestone company, became sales manager of the Star Rubber Co., in which Seiberling is heavily interested. This move, it is claimed, is the first step toward Partridge becoming general sales manager for the controlling company, with headquarters in Akron, which will operate the chain of small rubber companies.

Many former Goodyear officials who retired with Seiberling, and several who have since resigned from Goodyear, now are under negotiations with him, it is reported, and will be lined up for the new organization.

It is also believed that Seiberling is working on new types of tires in his New Castle plant. E. L. Davies, one of the Goodyear compounders and expert rubber chemists, has resigned and has been made development manager of the New Castle plant.

Seiberling has opened offices in the Akron business district and is in daily conference with men of the tire industry.

## Bill to Ban Truck Reimports Revised

### Graham Reduces Proposed Tariff Impost to 90%—Favored in House

WASHINGTON, Aug. 8—Favorable action is expected in the House on the revised Graham resolution, which has been reported by the House Committee on Ways and Means. The new measure provides for the imposition of a 90 per cent tax on all surplus war materials which have been sold abroad and reimported into this country. The bill is designed to check the flood of army motor trucks into the markets of this country.

The original bill as introduced by Congressman Graham, of Illinois, provided a 300 per cent assessment at customs, but he changed the rate to 90 per cent after consultation with members of the committee. The new bill is expected to prove as effective as the original, inasmuch as a tax of 90 per cent is sufficient to prohibit unfair competition by underselling of American motor truck dealers. The bill has a privileged status and will undoubtedly be passed this week. The committee's action is based upon the knowledge that some ad interim legislation was necessary at this time to stop the increase in reimportations of war supplies.

The Fordney bill which recently passed the House, carried a specific provision levying heavy rates on reimported material, but owing to the fact that the tariff bill will be delayed in the Senate, Congressman Graham offered the resolution. If this measure is passed by the Senate and signed by the President, it will bring to an end several months of consistent agitation in behalf of motor dealers. The original protests were filed from Los Angeles dealers' organizations where rebuilt cars were offered for sale at prices which could not be met by regular dealers.

## North Carolina Raises Insurance Theft Rates

CHARLOTTE, N. C., Aug. 10—The alarming increase in automobile thefts in North Carolina has caused insurance companies to place additional restrictions upon the insurance of cars against theft and to increase the rates an average of 35 per cent. A statewide investigation into activities of reported gangs of automobile thieves has been instituted.

While no estimate is obtainable as to the number of machines stolen monthly in the Carolinas, insurance men state that the increase in thefts within the last three or four months has been alarming, and that organized gangs have gotten rich through the theft of machines and their sale in distant cities and countries. It was said that one "company," with headquarters probably in Columbia, exported stolen machines to South Amer-

ican countries until the men engaged in the traffic were apprehended.

Virtually all the larger insurance companies have instituted the system of making a thorough investigation of the character and standing of the applicant before insuring machines. This is due to the numerous cases where the automobile owner has destroyed his own car for the purpose of collecting the insurance. The "moral risk" is receiving careful consideration by the companies.

## Cadwell Incorporates as Monarch Tractors

WATERTOWN, WIS., Aug. 8—E. D. Cadwell of New York, who recently purchased the assets of the bankrupt Monarch Tractor Co. of Watertown, Wis., for \$44,000, has incorporated the Monarch Tractors, Inc., under the laws of Delaware, with a capitalization of \$500,000 preferred and 5000 shares of common stock without par value. A Wisconsin charter has been granted. The application states that \$100,000 is represented by the investment at Watertown.

Cadwell, W. H. Foster and James A. Bell appear as incorporators of the new Monarch company. Cadwell was a principal stockholder and one of the principal creditors of the old Monarch company and its parent concern, General Tractors, Inc., of Paulsboro, N. J., which was petitioned into bankruptcy at the same time that the Monarch company was declared insolvent. The Watertown works have been in continuous operation on a limited scale since the financial difficulties came on, and since Cadwell took over the plant production has been materially increased.

## Creditors Get \$17,000 from Ferris Company

CLEVELAND, Aug. 10—William A. Ferris, one of the receivers of the Ohio Motor Vehicle Co., manufacturers of the Ferris automobile and trailer, states that practically all of the preferred creditors have been paid during the six weeks the receivers have been in charge. Approximately \$17,000 has been distributed to these creditors. The accounts payable now amount to \$158,000, while the assets total \$500,000. The receivership petition was a friendly action brought to relieve the company from suits threatened by small creditors. The application was filed by the Continental Motors Corp., which had a claim for \$32,000. It was filed after consultation with the company's management. Business has increased steadily since the receivers took charge.

## COAST TIRE TO EMPLOY MORE

OAKLAND, CAL., Aug. 10—The Coast Tire & Rubber Co. will increase its working staff to 500 persons Oct. 1. The company is now producing 125 tires a day, but, according to F. W. Neubach, special representative of the firm, will increase production to 750 tires.

## Ford's Tractor Plan Aids Salesmanship

### Sales Campaign Will Stimulate Better Business, Factory State- ment Declares

DETROIT, Aug. 8—Henry Ford's plan of pushing tractor sales through all dealers of the Ford Motor Co., regardless of whether located in the heart of an industrial district or in the center of a farming community, finds defense at the factory in the statement that the plan helps to develop salesmanship among the company's dealers.

No effort is required to sell Ford cars, is the factory view. Selling of tractors, however, particularly in some eastern cities where tractors have scarcely ever been seen in operation is considered another question. Of course it will require effort to sell them, admits the factory, but dealers and salesmen are supposed to exert themselves.

There is plenty of opportunity for tractor sales outside of actual farming districts, holds the company. All sorts of pamphlets showing sales opportunities are constantly being mailed to dealers setting forth work in which tractors can be used advantageously aside from farm work. In the opinion of the company, tractors could be far more serviceable in many forms of general contracting and road construction work than horses.

It was further declared that while company experts were constantly at work developing new fields in which tractors might be used, it was part of the dealer's work to discover a few outlets for himself and put sales over. Practically every inch of the United States has been carefully analyzed, the company declares, and no tractors are being shipped where there are no sales possibilities. This holds just as good for New York City as for Jones Crossing.

Notwithstanding the contentions of the factory, there is much discontent among Ford dealers because of arbitrary shipments of tractors which the dealers do not want and which they insist they cannot sell. It is understood that in some cases where the tractors have been refused, car shipments have been withheld. In a few cases, at least, Ford agencies have been given up because of the tractor plan.

## Ford Dealers Evolve Plan to Sell Tractors

NEW YORK, Aug. 9—Metropolitan distributors of Ford cars who have been compelled by the company to accept shipments of Fordson tractors in order to get the automobiles, have evolved the plan of fitting the tractors with rubber tires and other special equipment with the idea of promoting their use on docks, in warehouses and for other industrial purposes. Considerable work also has been done in adapting the machines for snow removal and other municipal work.

## May Have Truck Lines for Coast Terminal

### Consider Motor Transportation for Proposed San Francisco Bay Port

SAN FRANCISCO, Aug. 8—A combination of municipal and private enterprises has completed surveys, plans, engineering estimates and reports, with the approval and consent of the Federal Government, for the construction of a port terminal on the eastern shore of San Francisco Bay.

This deep water improvement, which has been incorporated as the Pacific Port Terminal, Inc., will cost several millions of dollars. It is intended to furnish adequate facilities for the handling of a large part of the foreign trade of the United States, a commerce valued in 1920 at more than \$2,000,000,000 and which, it is estimated, will be doubled within the next 5 years.

One of the most prominent features of this terminal—which will have 140,000 lineal feet of berthing space, with 30 feet of water at mean low tide—is the serious consideration which has been given to equipment and facilities for the accommodation of motor truck lines throughout the terminal and on the 6000 acres of manufacturing and industrial sites on the mainland directly back of the terminal.

#### Five Main Highways

Five main highways, leading through Berkeley, Emeryville, Oakland and Alameda, averaging 80 feet in width, lead to the site of the terminal. Each will be continued in loop form through the industrial section on the mainland, and from this loop provision is made for paved streets equally wide to every wharf shed in the 3,000,000 square feet of wharf shed space on the filled-in bulkhead of each unit and to every warehouse on the 3,500,000 square feet of warehouse space on the filled front of the mainland just back of the projecting quay of each unit.

There will be two wide paved ways running out each quay to the head of the bulkhead, for the use of automotive vehicles, so that motor truck lines may deliver their freight direct to the shipside in exactly the same manner as continental freight cars. Special loading and unloading machinery for motor trucks is included in the plans for the equipment of each quay, and motor trucks will be handled in the same manner as freight cars, with clearance kept for them throughout the wharf sheds and in the warehouses. While classification yards will not be necessary for motor trucks, large space has been provided alongside the car yards for motor truck use.

#### Establish "Free Port"

It has been considered necessary to establish a foreign trade zone (free port) on this terminal. There being no inland shipments from this zone, railroad tracks

will not be necessary and motor truck distributors are expecting that all this large traffic will create a considerable demand for trucks.

Motor truck lines operating out of San Francisco Bay into northern California and Nevada will have direct connection with trans-Pacific steamers instead of having to ferry across the bay for their cargoes. This will mean a big saving in operation and will probably increase the number of fleets operating.

Plans for the equipment on the quays include ramps on which motor trucks can be driven directly onto any deck of a berth freighter, loaded and driven off again, in case there are any difficulties in the way of loading or unloading a cargo shipside. This will also mean a reduction in operating costs.

Approximately 10,000 miles of highways suitable for the operation of motor trucks and on which motor trucks are now operating will be given direct connection with deep-sea commerce by the construction of the first unit of the new Port Terminal at Berkeley. Connection will also be made between motor truck lines and inland waterways and navigable streams entering San Francisco Bay, as well as with all towns on the 116 miles of water front of that bay.

## May Merge Two Western Automotive Associations

SPOKANE, WASH., Aug. 8—Negotiations contemplating a consolidation of the Washington Automobile Chamber of Commerce and the Washington Automotive Trades Association was the most important subject discussed at the annual meeting of the latter association. The consolidation is expected to create a body of greater power.

Discussion of the margin of profit and contracts occupied a liberal share of the attention of the delegates to the annual convention. Several speakers declared that the dealers need a larger margin on their goods and if they hope to get the backing from the banks that they expect the margin must be increased. It also was argued that most of the contracts under which dealers operate at present are unwarrantably unfavorable to them. The association members want a contract that cannot be taken from them if they live up to its provisions. Crystallization of sentiment on these questions was urged.

#### OLIVER-BARTH MERGER

MILWAUKEE, Aug. 8—The recent change of corporate style of the Oliver Mfg. Co., Milwaukee, to Oliver-Barth Jack Co., marks the formal consolidation of the Oliver company with the Barth Mfg. Co., both specializing in the manufacture of lifting jacks and similar automotive equipment. The Oliver company, originally established in Chicago, was acquired by Milwaukee interests identified with the Northwestern Malleable Iron Co. of this city about a year ago and the plant was moved to Milwaukee. Now the Barth company has been purchased by the same interests.

## Electric Railways After Motor Trucks

### Association Opens Nation-wide Propaganda Campaign on Tax Question

NEW YORK, Aug. 10—A nation-wide propaganda campaign in opposition to the widespread use of motor trucks is being conducted by the American Electric Railway Association.

The slogan of the campaign is: "Use the trolleys—Save the highways."

The chief argument advanced against trucks is that they wear out the highways and do not pay a fair proportion of taxes. The campaign is being conducted by a committee of 100, representing traction companies in all parts of the country. This committee, acting through local electric railway companies, supplies the newspapers with "canned" editorials and other material which purports to show why the trolley companies are not being treated fairly because they are compelled to pay taxes and the motor bus freight and passenger car companies have no obligations of this character beyond their license fee.

#### Make Vigorous Efforts

The efforts of this committee probably are responsible for the vigorous efforts which are being made in many sections of the country, particularly in Connecticut, to curb the operations of motor bus lines which have cut deeply into the profits of street car companies by offering lower rates of fare as well as more convenient and efficient service.

A similar campaign against the use of motor trucks and tractors has been instituted by the Horse Association of America, which contends that farm work as well as the hauling of merchandise can be done more economically and expeditiously by the use of horses.

The latter campaign is just getting under way but it is understood it will attain vigorous proportions.

## Immel Stockholders Name New Directors

COLUMBUS, OHIO, Aug. 10—The stockholders of the Immel Co., which recently purchased the large automobile body plant as well as a large amount of materials from the receiver of the company, met Aug. 3 and named the following board of directors for the new company: A. G. Gilmour, G. P. Hickie, John W. Dinsmore, J. C. Goeller, F. E. Kocher, C. W. McFarland and V. W. Moss.

A name will soon be selected and incorporation papers filed with the Secretary of State. Some question as to the name of the new company has arisen. With the filing of incorporation papers, steps will be taken to put the plant in active operation. It is likely that J. D. Potter, formerly with the Kilbourn & Jacobs Co. of Columbus and later with the American Motor Truck Co., of Newark, will be made general manager.

## Rickenbacker to Take Over Everit Plant

New Car Will Be Exhibited at New York and Chicago Shows

DETROIT, Aug. 10—Rickenbacker Motor Car Co., the latest entrant into the Detroit automotive field, will take over the Everit Bros. plant in from sixty to ninety days and will at once tool up for production the first of the year. The first Rickenbacker cars will be exhibited at the New York and Chicago shows and at all leading shows of the season.

The Everit plant, which is owned outright by Byron F. (Barney) Everit, is turned over by him to the Rickenbacker company, of which he is president, for a consideration of \$2,000,000. One million of this is paid in stock of the new company and he has subscribed for \$1,500,000 more. In the incorporation of the company, as filed here, Everit is shown as practically sole owner of the company's stock but this later will be apportioned to the other men associated in the company, with Everit retaining control.

The automobile painting and trimming business of Everit Bros. will be removed to another plant in Detroit, for the purchase of which Everit is now negotiating. Three plants are under consideration, he said, one of which will be selected in the near future.

### Sufficient Working Space

Present buildings of the Everit plant on Harper Avenue will afford the Rickenbacker company sufficient working space for the production of 20,000 to 25,000 cars a year. There is also unoccupied acreage included in the purchase to permit of tripling or quadrupling present capacity should it be required.

When the removal of the equipment of the Everitt plant is started the installation of the Rickenbacker machinery will follow at once. This will be done rapidly, for the company has economized on time by having patterns made for the equipment required, as the development of the car progressed. This has covered two years and ten months and the company is ready to-day with all its patterns for machinery and machine tools.

Every bit of the equipment will be specialized to the last degree, according to the company's plans. Contracts for everything it will require are now being placed. It will start off the first of the year with an absolutely clean slate, with all equipment and material bought at what Everit regards as absolutely bottom prices. In his opinion material prices are now as low as they will get and may show slight advances from this time on.

Details as to prices and specifications of the new car will not be released until the cars are placed on exhibition at the shows. It will be a medium priced car,

Everit said, and will be up to the minute in every particular. He regards the outlook for the company as especially bright and declares that its formation now, with material prices at their lowest, will prove particularly helpful in making the car a big factor in the trade.

## Bakelite Wins Ruling in Suit Over Patents

NEW YORK, Aug. 8—Judge Chatfield in the United States District Court has handed down a decision sustaining the contentions of the General Bakelite Co. of this city in its suit against the General Insulate Co. of Brooklyn for alleged infringement of patents. The decision is in favor of the plaintiff and declares that the three patents in question, known as the heat and pressure patent, the indurated product patent and the molding patent, all have been infringed by the defendant. The General Insulate Co. used products manufactured by the Redmanol Chemical Products Co. of Chicago but in his decision sustaining the validity of the Bakelite patents, Judge Chatfield said:

"The record shows that in fact the Redmanol company has stood behind the defendant in the trial of this action, and in so far as investigation of the prior art and discussions of questions of patentability are concerned, the Redmanol company has as freely and fully presented its evidence as if the action had been against the Redmanol company for infringement of the plaintiff's patents in the manufacture of the synthetic gum itself."

## General Motors Adds to List of Stockholders

NEW YORK, Aug. 8—The increase in the number of General Motors stockholders, which has been in progress for the past year, continues. At present there are approximately 66,000 stockholders of all classes, compared with 59,000 three months ago and 31,000 a year ago. The detail of the number of stockholders follows:

Classes of Stock:	Number of Stockholders	
	August, 1921	May, 1921
6% Preferred.....	3,170	3,164
6% Debenture.....	10,107	9,934
7% Debenture.....	9,046	7,847
Common .....	43,001	37,922
	65,324	58,867

### TIRE MAKERS WILL MEET

NEW YORK, Aug. 5—The first of the quarterly meetings of the tire manufacturers' division of the Rubber Association of America will be held Sept. 22. The executive committee will hold its regular monthly meeting the previous day and such recommendations as may be formulated then will be considered at the division meeting. Two important questions under consideration are mileage adjustment and protection against price decline.

## Pennsylvania Opens Big A.E.A. Campaign

Jobbers Dine and Hear "Pep" Addresses—Plan Week of Activity

PHILADELPHIA, Aug. 10—Jobbers of the eastern Pennsylvania district successfully launched their part in the national sales promotion movement of the Automotive Equipment Association at a dinner to-night. Upward of 150 proprietors, executives and salesmen of nine jobbing houses met at the rooms of the Automobile Trade Association and after their repast listened to four inspirational and informative addresses on the opportunities offered jobbers and their salesmen to increase their own profits and those of manufacturers and retailers by aggressive participation in the sales promotion campaign.

One of the speakers was Harry C. Spillman of the Remington Typewriter Co.'s educational department, who in the main repeated the brilliant talk on development of personality which he made at the Mackinac Island convention of the Automotive Equipment Association. E. J. Cattell, city statistician of Philadelphia, talked on the mental and moral qualities necessary to successful salesmanship.

T. F. Cullen, managing editor of the *Automobile Trade Journal*, spoke of the need for a campaign of education throughout the trade and suggested methods of participation in it by jobbers and their salesmen.

Neal G. Adair, editor *Motor World*, basing his talk on observations recently made in trips with jobber salesmen and in investigations of accessory selling activities of dealers and garagemen, outlined a program of activity which would enable jobber organizations to attain momentum in the sales promotion movement prior to issuance of detailed instructions for the work from association headquarters.

Jobbers participating in the meeting were: Gaul, Derr & Shearer Co., J. H. McCullough & Son, George W. Nock Co., Cahall Motor Supply Co., Berrodin Rubber Co., Manufacturers Supplies Co., Roberts Electric Supply Co., Standard Supply & Equipment Co., all of Philadelphia, and General Auto Supply Co. of Lancaster.

### EDITORS SEE NEW DURANT

NEW YORK, Aug. 10—At a luncheon served at the Long Island City assembling plant of the Durant Motors Corp. about one hundred automobile editors from New York, Brooklyn, Newark and other nearby cities inspected the new Durant car previous to its public presentation on Broadway at the showrooms of the Poertner Motor Car Co. W. C. Durant, the president of the company, made a short address in which he told briefly his own connection with the automobile business, and engineering and other officials spoke.

## Wisconsin Opens War on Federal Motor Tax

**Manufacturers, Dealers and Owners Band in Opposition to Measure as Added Burden**

MILWAUKEE, Aug. 10—The storm of opposition and protest that has arisen in the automotive industries and among users against the proposed national tax on passenger and commercial cars has taken organized form in Wisconsin under the leadership of associations of manufacturers, dealers and owners. Jesse A. Smith, Hudson and Essex distributor, who is president of the National Automobile Dealers Association, said:

"While both the National Automobile Dealers Association and the National Automobile Chamber of Commerce have representatives at Washington fighting to defeat this proposition, we need the united protest of owners added to ours if this tax is to be defeated. While Congress is reported to be lukewarm on the proposal of Secretary of the Treasury Mellon, which is reported to have the support of the President, we are apprehensive, for it is a fond idea of legislators to regard the motor car as a 'luxury,' that owners are wealthy persons, and thus may be taxed at will. Owners now pay a 5 per cent tax on new cars, are required to pay State and sometimes local license fees, personal property taxes, and State and local road taxes. Seventy-five per cent of the passenger cars in this country are used for business, and trucks certainly are business cars. We believe the motor vehicle already is overtaxed, and no additional burden should be imposed."

Bart J. Ruddle, executive secretary and manager of the Milwaukee Automotive Dealers Association, said: "We are maintaining good roads in Wisconsin and paying heavily for them. Why should we also be called on to help some undeveloped State build its roads? We have repeatedly made our case known to members of Congress and we will not halt our efforts in opposition to the proposed Federal tax until it is definitely killed. Vigorous protests also have been made from other parts of the country. There are 9,260,000 owners in the United States and I doubt if Congress will dare to antagonize them further. In addition to all other taxes, motor trucks are compelled to pay an 8 per cent transportation tax and it is not right and proper that the great national transportation system being built up with commercial vehicles should be penalized more than it already is."

### DETROIT EMPLOYS MORE MEN

DETROIT, Aug. 10—Reports by the 79 members of the Employers' Association for the week ended July 26 showed 117,572 men on the payrolls as compared with 115,397 for the previous week. The number of part time workers was practically the same as the week before.

### LORD NORTHCLIFFE PRAISES BRITISH MOTOR BUS; CALLS U. S. SLOW

WASHINGTON, Aug. 10—Lord Northcliffe, the eminent British publisher, who is now on a tour of the world, is a warm friend of the motor bus. In an interview while he was in this city he declared he could not understand why Americans had been so slow to grasp the possibilities of this form of transportation. He stated that in this respect American cities were lagging far behind those of Europe where motor bus transportation had been brought up to a high standard. He pointed out that in London, during the rush hours, motor buses provide practically incessant and ideal service.

### Palmerton to Manage Foreign Trade Bureau

NEW YORK, Aug. 10.—As a part of its plan to co-operate with the Department of Commerce, the Rubber Association of America has granted a leave of absence to P. L. Palmerton, manager of the Foreign Trade Bureau of the association, so that he can accept the position of chief of the rubber industrial division of the Bureau of Foreign and Domestic Commerce.

The Bureau of Foreign and Domestic Commerce proposes to establish from 12 to 15 sub-divisions, each of which will maintain and strengthen the contact between some particular industry and the bureau. The absence of Palmerton will not mean any lessening of foreign trade activities by the Rubber Association. He intends to carry on much of this work in Washington, and if he finds later that this plan is impracticable the work will be handled here.

### Anderson August Sales Will Run Ahead of 1920

DETROIT, Aug. 10—Business in high-class custom built cars promises well for fall and winter months, declares General Sales Manager C. B. Shanks of the Anderson Motor Co., Rock Hill, S. C., who was in Detroit this week. August business with the Anderson company will run ahead of sales in August, 1920, he said, after falling slightly under the 1920 totals in July. New territories are being opened by the company in many sections of the country, through the appointment of distributors.

### HUNT QUILTS NEW YORK REO

NEW YORK, Aug. 8—James J. Hunt, vice-president and general manager of the Reo Motor Car Co. of New York has tendered his resignation effective Sept. 1. Hunt has not been in the best of health lately. He has been with Reo in the New York territory since 1915.

## 'Midget' Car Appears on Japanese Roads

**Built to Meet Peculiar Conditions—De Luxe Engine Used Made in U. S.**

SEATTLE, Aug. 10—A new automobile of Japanese production known as the "Midget" was recently placed on the market in Japan. The car was built to meet the peculiar conditions of Japan, taking into consideration local conditions, such as poor roads, narrow streets, high price of fuel and limited buying power of public. The car, which is very small, as its name implies, with a wheel-base of only 84 inches, is manufactured at the Shibaura works of the Far Eastern Automobile Co.

The total weight of the car is only about 850 pounds. The top of the door is 37½ inches from the ground. The engine is a "De Luxe" air-cooled V-twin, developing 12 horsepower, and is made in Indianapolis. Cooling is aided by a belt-driven fan, placed directly in front of the engine behind the false radiator. Ignition is by Bosch high-tension magneto, and lubrication by automatic gear pump, assisted by a hand-operated oil pump. The transmission is selective, with three forward speeds and one reverse. The transmission case is mounted far enough behind the engine to allow for a transmission brake between the two units. The drive is taken from the transmission by a propeller shaft to a live rear axle. Drive is taken through radius rods arranged on the three-point system, somewhat similar to that employed by the Ford.

The body design follows the French practice. The front seat is large enough for the driver only, but the rear seat accommodates two with comfort.

The makers state that the car will average from 25 to 35 miles per gallon, and that its maximum road speed is about 30 miles an hour.

### Zee-Zee Rubber Files Bankruptcy Petition

TRENTON, Aug. 10—The Zee-Zee Rubber Co., manufacturers of automobile tires and tubes and doing business through a chain of stores in New York, the New England states, New Jersey and Pennsylvania, to-day filed a petition in bankruptcy in the United States court here. The liabilities are scheduled at \$293,552 and the assets at \$434,964.

The general business depression is responsible for the failure, according to Herbert P. Backes, attorney for the corporation, who filed the petition. More than one thousand creditors are listed. The plant of the company, at Yardville, a few miles south of Trenton, was built a few years ago and is valued at \$392,000, according to the petition. The concern ceased operating the plant the first of this month, throwing many men out of work.

## Lesson Is Forced Home by Tax Plan

### Mellon Proposal Teaches Congress Owners Consider Cars Essential

WASHINGTON, Aug. 9—One of the outstanding developments of the proposal of the Secretary of the Treasury for a flat levy of \$10 on automobiles and trucks is the realization that has come to Congress that 10,000,000 automobile owners regard their machines as essential to their welfare and prosperity. There has been an unmistakable reaction against the Treasury plan and Congressional leaders were quick to voice the sentiment. It now appears that if the automobile is assessed as a means of additional revenue it will be graduated according to horsepower. It is significant to note that nowhere in the tax discussions has the repeal of the excise taxes been favorably mentioned.

The latest tax proposal has awakened the automobile owner to the fact that there is reasonable ground for the claim of the National Automobile Chamber of Commerce that the industry has been singled out for so-called "stigma taxes."

Heretofore, the average automobile owner paid little attention to the fact that he paid a large sum in taxes when the car was purchased. Now that the Treasury wants another assessment, the car owner has figured the total taxes and discovered that national, State, municipal and road taxes placed him in a distinct class in that the total exceeded any other group. The net result is that the industry has gained an ally in fighting discriminatory taxation.

The Secretary of the Treasury has quite unwittingly made the country cognizant of the true position of the automotive industry as it relates to taxation and strengthened it accordingly.

## Myers Spark Plug Will Move Plant to Detroit

DETROIT, Aug. 9—The plant of the Myers Spark Plug Co. will be moved from Toledo to this city, following arrangements for the financing of the new Detroit Ignition Co., which has taken over the Myers company. The new company will have a capitalization of \$300,000, part of this having been paid over to stockholders in the original company.

It is expected that manufacturing will begin in Detroit soon after the first of the year. Equipment will be installed to permit of a 5,000,000 annual production. It is planned to make intensive sales efforts in leading cities of the country, one city to be taken at a time beginning with Detroit. Advertising will feature the self-cleaning patented mechanism of the plug.

Officers of the company are: C. F. LaFond, president; C. C. Starkweather, vice-president; Clarence E. Lehr, secretary, and Louis H. Turrell, treasurer.

### "PRESENT AND FUTURE" THEME OF M. A. M. A. MEETING SEPT. 14-16

NEW YORK, Aug. 8—The central theme of most of the papers and discussions at the credit convention of the Motor and Accessory Manufacturers Association, which will be held at Detroit, Sept. 14, 15 and 16, will be, "Business conditions in the automotive industry and prospects for the future." This subject will be taken up in an open forum discussion from the standpoints of the raw material producer, the parts manufacturer, unit and equipment makers, vehicle manufacturer and dealer. Prominent executives in various branches of the industry will lead the discussion.

Another stimulating feature of the convention will be a symposium on "Selling strategy to bring the automotive industry back to normal." This topic will be discussed by sales and advertising executives.

## Receiver Is Named for Kelly Tire and Rubber

NORWALK, CONN., Aug. 8—Former Congressman Augustine Lonergan of Hartford has been named by Judge Edwin S. Thomas of the United States District Court as receiver for the Kelly Tire & Rubber Co. of New Haven. The appointment was made on petition of Attorney Benedict M. Holden of Hartford, representing the stockholders' protective committee, consisting of Vice-President Nathan D. Prince of the Hartford-Connecticut Trust Co. of Hartford, President C. L. Holmes of the Waterbury Trust Co. and President John T. Manson of the First National Bank of New Haven.

Lonergan displaces the Bridgeport Trust Co., Attorney A. H. Barclay of New Haven and Moses Ullman of New York, as joint receivers of the company, under appointment of the Superior Court. The petition for Congressman Lonergan's appointment was granted on the ground that the directors of the tire company committed an act of bankruptcy in having the receivers appointed in the State court and, being a bankruptcy case, it became a matter for the Federal court.

### FISK ACTION DEFERRED

CHICOPEE FALLS, MASS., Aug. 9—Special meetings of stockholders of the Fisk Rubber Co. and the Federal Rubber Co. were held here to-day to consider refinancing proposals but adjournment was taken without definite action. The plan calls for the purchase by the Fisk company of all the assets of the Federal company as well as the Ninigret Co. The number of proxies received from stockholders since the proposal was submitted is said to have been encouraging.

## Truck Industry Asks Repeal of Burke Law

### Committee Appeals to Governor to Amend Measure Limiting Weights

CLEVELAND, AUG. 9—A committee of five that represents every phase of the motor truck industry in Ohio went to Columbus to-day and asked Governor Harry L. Davis to provide means for permitting the Burke law limiting the weight of motor trucks to be amended at the special session of the general assembly, which will be held next January.

The committee also discussed with Governor Davis plans for the filing in court of a friendly suit to test the constitutionality of the law, which becomes effective Sept. 5. The Governor was told that the Ohio truck industry and users of trucks were done a great injustice when the bill was passed and they hope to work out a plan of action with him whereby an early amendment to the law may be made and operation of the law deferred until it is changed.

### All-Round Committee

Members of the committee are P. A. Lewis, Springfield, of the Kelly-Springfield Truck Co.; W. W. Williams, Columbus, representing dealers; W. C. Free-lock, of the Liberty Cartage Co., Cleveland, representing users of trucks; H. A. Waddle of the Goodrich Tire & Rubber Co., representing tire manufacturers, and J. S. Schindle of Cleveland, representing business users of trucks.

Lewis is chairman of the committee, which was named by T. R. Dahl, secretary of the White Co., at a recent meeting in this city.

The committee informed the Governor that if the bill becomes a law these things will happen to the truck industry, users of the vehicles and consumers:

Approximately 15,000 five and seven-ton trucks will be eliminated as a transportation medium; \$2,000,000 worth of trucks will have to be scrapped; transportation costs will be increased \$5,000,000 because of the larger number of trucks required to haul traffic now handled and the increased number of employees; milk companies will have to pay one cent a gallon more for transporting that product to the cities and consumers and producers generally will have a new load put on their shoulders.

### What Measure Means

Under the Burke bill loads allowed on highways are reduced to 20,000 pounds including the truck; weight per inch of tire width is reduced from 850 pounds to 650 for pneumatic tires. Steel tired vehicles are allowed to carry 24,000 pounds and the truck people say this is ridiculous as the steel tired vehicle is harder on improved roads than is the other class of vehicles. When the Governor issues his call for the special session of the Legislature, the committee asked him to set forth amendment of the Burke bill as an order of business.

## No Dearth of Sales in Atlanta Field

### August Business Holds Up with Other Months—Registration Is Heavy

ATLANTA, GA., Aug. 9—If registration figures at the State Capitol are any kind of barometer of sales conditions, the August total of retail sales in Atlanta will be up to that of any previous month this year. The first week of August there was an average of about 70 licenses issued daily, this including new and used passenger cars and trucks. The trucks are greatly in the minority, while about half of the motor car sales are of new cars. No re-registration is required in Georgia and therefore all of these are bonafide sales, this report covering retail trade in Atlanta only.

As many of these sales were made during July, the buyers waiting until after July 31 to secure their licenses, total sales for the past five weeks have been in the neighborhood of 700 new and used motor cars and trucks.

#### Cotton Price Rises

There has been a sudden and substantial increase in the price of cotton because of the Government's report on the low condition of this year's crop, and as a result automotive sales in the rural districts and smaller communities are expected to experience considerable stimulus within the next few weeks. Cotton went up about two cents per pound the first week of August.

Optimism as regards the future outlook for the industry in this section was the keynote of the annual sales convention of southeastern Buick dealers held at the Capital City Club in Atlanta. About 150 Buick dealers from Georgia, Florida and Alabama attended the three group meetings, virtually all of them stating they have noted a steady improvement in their business since June 1, with every promise that conditions will continue to improve gradually from now on.

Official announcement of sales by the Buick dealers in the three States since June 1 was made by Byron H. King, manager of the southeastern branch in Atlanta, who gave the number of new cars sold since that date as approximately 1000.

### Passenger Car Sales Improve in New York

NEW YORK, Aug. 10—Passenger car sales in the Metropolitan district have been a little better so far this month than was expected by dealers who had carefully reviewed their books for August in pre-war years. Turnover of course is of smaller volume than in July but the decline has not attained the importance of a slump by any means. Buick, Studebaker and Dodge are still selling far ahead of supply as they were

in June and July and several other cars are still running strongly.

Every week dealers have been added to the list of those who have all but stopped trading. Buying in the used car market is so close that quite a number of dealers have been taught a sharp lesson on the subject on over-allowance. A few are still taking in owners' cars at figures plainly above what they can get for them but the practice is far less widespread than it was two or three months ago. Several dealers are frankly telling new car prospects to go out and sell their used cars themselves unless they are willing to take a reasonably low price for them.

The question of operating costs is troubling several of the largest distributors who are facing renewals of sales-room leases at rental figures anywhere from 50 to 100 per cent above what they were when they signed their present contracts five years ago. It is probable that there will be several removals this fall and one or two dealers may go around the corner in one of the side streets off Broadway.

### Philadelphia Looks for Good August Business

PHILADELPHIA, Aug. 8—A few leading automobile dealers and distributors have asserted that July, particularly toward the end, proved one of the best months in the year for new cars, but for the majority of agencies the period was below June. All agree, however, that August sales, because of an extra spurt of energy, particularly noticeable among nearly all organizations, promise well.

Truck sales are so flat that several dealers talk of dropping them and concentrating on something else.

Repair parts are not selling well, except in rather isolated instances, where special efforts have been made to push them.

### Business Conditions Are Satisfactory in Washington

SEATTLE, Aug. 10—While there has been a slump in the movement of cars in several sections of the State during July as compared with the previous month, business conditions as affecting the automotive trade in Washington are satisfactory. Conservative optimism over the outlook for the immediate future and confidence in the consistent improvement of business conditions was expressed both at the annual meeting of the Washington Automotive Chamber of Commerce recently held in Spokane, the annual convention of the Washington State Automotive Trades Association which followed at Tacoma, and the Northwest Buyers Week at Seattle.

The volume of orders booked by merchants generally at the Buyers Week at Seattle far eclipsed expectations and may well serve as an indication of the improving conditions in the State of Washington.

## Columbus Business Continues Upgrade

### Medium Price Cars Selling Best —Rumor of New Model Hurts Ford

COLUMBUS, OHIO, Aug. 10—A continued improvement in the demand for passenger cars is reported from practically all of the agencies and distributors of Columbus. The business is now definitely on the upgrade. The only exception to the general improvement is the demand for Fords, which has fallen off materially since the newspaper publication of reports, since denied, of the coming of a new model with a possibility of new prices. With the publication of these stories business fell off with a thud and efforts of the salesmen of the various Ford agencies have not succeeded in securing normal business.

In other makes trade is stimulated by the recent price reductions and agencies generally are fairly busy. This applies to cars ranging in price from \$800 to \$3,500 and in some instances higher-priced cars. But the usual run of business is now for the medium-priced lines and these are showing the best improvement.

The unemployment situation in Columbus is better than was the case several weeks ago. This is an encouraging factor and presages a continuation of the improved demand. It is believed that the worst of the slump is now over and dealers and distributors are making plans accordingly.

#### Rural Districts Slow

In the country districts trade is still slow, although some improvement is reported. The crop prospects are slightly better with recent heavy rains and the farmers are showing some disposition to come into the market. But little trade is anticipated in the rural sections for some time, as the farmers are not having a prosperous season.

Truck business is still slow with the exception of the demand for light delivery wagons. The heavy truck business is at a standstill and little hope of immediate revival is seen. Heavy haulers have a good supply of trucks and they are not coming into the market as a result.

#### SHOW MANAGERS NAME ADAIR

CHICAGO, Aug. 10—The board of directors of the National Association of Automobile Show and Association Managers has unanimously chosen Neal G. Adair, editor of Motor World, secretary and treasurer. He succeeds Ray W. Sherman, who resigned when he left the executive editorship of the Class Journal Co. to become merchandising director of the Automotive Equipment Association. E. E. Peake, secretary of the Kansas City Motor Car Dealers Association, is president of the Show Managers and Secretaries organization.

## Coast Sales for July 20% More Than June

—  
**Generally Favorable Condition in  
Northern California—Rural  
Prospects Are Good**

SAN FRANCISCO, CAL., Aug. 10—A rather unusual, yet generally favorable condition developed in the merchandising of automotive vehicles, particularly passenger cars, during July in northern California. While retailers reported sales about 20 per cent above those of June, distributors announced that the ratio of country sales to city sales, usually about three and one-half to four to one in favor of the country sales, had fallen to three to two.

To counterbalance this apparent decrease in country sales, however, distributors said they had reports from dealers throughout the rural districts, indicating that prospects were more numerous than they had been in eight or ten months. The condition these outside dealers reported is that the farmers and others engaged in handling products of the soil, are waiting until the money begins to come in for this year's crops before buying passenger cars.

Both country dealers and distributors interpret this as meaning that sales will be considerably better in the latter part of August and throughout September than they have been for some time. The people are going to buy cars, according to these distributors, but they are planning to pay cash for them, and they have to wait until they have the cash to pay. The surprising factor is that so many people are buying, for, in general, sales are considerably above the June record, and are better than they were in July a year ago.

The dealers' associations throughout northern California are highly pleased with general merchandising conditions, and expect improvement ranging all the way from 100 per cent in the centers of distribution in the agricultural sections of the State, to 50 per cent in the largest city—San Francisco. The best feature of the whole situation, however, is that the dealers are not "living on hopes," but are going right along selling cars in sufficient numbers to show good figures on the right side of the ledger. Cash sales are more numerous than they usually are at this time of year, and more prevalent than they have been at any season within the past eighteen or twenty months.

### SEVERNS KNOX RECEIVER

MT. VERNON, OHIO, Aug. 10—F. W. Severns, former county treasurer, has been appointed receiver for the Knox Tire & Rubber Co. The petition for a receivership was filed by Edward Elford, who claimed to have a mechanics lien on the property for \$6,754. Severns will continue operation of the plant under the direction of the court.

### AUTOMOBILE "SAFETY-FIRSTS" WILL FEATURE TRAFFIC CONVENTION

OAKLAND, CAL., Aug. 10—Equipment and "safety-first" men in the automotive industry will have their innings at the annual convention of the International Traffic Officers Association here, Oct. 24 to 29. An exhibition of safety devices, automobile equipment intended to make driving safer and easier, fire-prevention outfits for automotive vehicles, and all manner of safeguards for machinery will be open to the public in the Municipal Auditorium of Oakland, in which the convention will be held. The fire departments of all the cities around San Francisco Bay will demonstrate fire-fighting with the latest automotive equipment; truck fleets will be shown in operation; the handling of heavy traffic on improved highways with minimum damage to paving and other surface will be discussed, and all in all, the automotive industry will play a very large part in the convention.

## Cleveland Employing 3.6 Per Cent Less Men

CLEVELAND, Aug. 10—Cleveland automobile and accessory manufacturing establishments were on July 30 employing 3.6 per cent fewer persons than on June 30, according to a survey made by the Committee on Labor Relations of the Chamber of Commerce.

Twelve manufacturing establishments reported in the survey of the automobile industry and on July 31 they were employing 7463 as compared to 7742 on June 30.

Employment figures in all industries show that pay rolls on the average remained about stationary during the month of July. There were 54,165 employed June 30, in the 99 establishments that reported in the survey, while at the close of July there were 54,161.

In the metal and metal products other than iron and steel there was no loss; in the iron and steel industry the loss was 1.3 per cent; a gain of 10.4 in the food and kindred products; a gain of 1.1 per cent in textiles and their products; a gain of 7.3 per cent in lumber and its manufacture; a gain of 5.9 per cent in paper and printing and a gain of 5.2 per cent in chemicals and allied products.

### WEIGEL LEHIGH MANAGER

NEW CASTLE, PA., Aug. 5—D. W. Weigel has assumed the management of the Lehigh Tire & Rubber Co., formerly the New Castle Rubber Co., recently purchased at receiver's sale by F. A. Seiberling. It is understood Seiberling will come here personally in a few days to supervise the resumption of operation. It is proposed to make about 500 tubes a day.

## Unit Parts Orders Preface Sales Gain

—  
**General Business Spurt Declared  
Certain to Follow Turn of  
the Year**

DETROIT, Aug. 10—General improvement in passenger car business in September and October, with gains for each month over the month before, is indicated in orders now being placed with some of the leading unit part makers. November and December are expected to show a falling off, but a general sales spurt all along the line is declared certain to follow the turn of the year and the opening of the show season.

Many of the car manufacturers are already planning a manufacturing schedule in anticipation of spring business, which they will get under way in December. Some of the others are known to be outlining a schedule which will start off promptly the first of the year, while the remainder will await the opening of the actual selling season and trust to ability to speed up quickly, to meet demands.

All of these arrangements depend to a large extent upon the financial position of the different companies. The stronger companies will start to stock up first and will build a little higher than the others. There has been much conjecture on just what the attitudes of the companies would be toward preparing for spring sales, and apparently the first impression that little stocking would be done is proving wrong. The spring of 1922 will find, however, many thousands less cars piled up than was the case in '21.

Passenger car production in all Detroit factories to-day is being held strictly to sales levels, and there will be little accumulation of cars before December. This is far different from the situation last year which resulted in the storing up of so many cars over the fall and winter months.

There is little sign of parts business from truck manufacturers.

### WESTCOTT MAKES CUTS

SPRINGFIELD, OHIO, Aug. 10—The Westcott Motor Car Co. announces reductions in its various models effective Sept. 2. In the "lighter six" line the roadster and touring car will be reduced from \$2,290 to \$1,890; the sport model from \$2,390 to \$1,990; the coupé and sedan from \$3,390 to \$2,890. In the "larger six" line the seven passenger touring car will be reduced from \$2,990 to \$2,090; the sedan from \$4,590 to \$3,490 and the limousine sedan from \$4,690 to \$3,690.

### FORD MAY GET SHIPYARD

BOSTON, Aug. 10—The Ford Motor Co. may buy the Victory plant at Squantum, an emergency shipyard, if Mayor Bradford of Quincy is successful in completing negotiations on behalf of the Government.

## Pierce-Arrow Trucks and Cars Reduced

**Commercial Bodies Already Down  
and Passenger Cars to Be  
Cut Sept. 1**

BUFFALO, Aug. 10—The Pierce-Arrow Motor Car Co. has made sharp reductions in the prices of its trucks. The prices follow:

	New Price	Old Price
2 ton.....	\$3200	\$3750
3½ ton.....	4350	4950
5 ton.....	4850	5700

Prices of various models of Pierce-Arrow passenger cars will be reduced Sept. 1. George M. Graham, vice-president of the company, said to-day this would be the first drop in prices since rising costs forced them up. Graham declined to state what the new prices would be, but added that they would be announced next Monday. It is learned, however, that the touring car will be reduced \$1,000 from \$7,500 and the closed models from \$500 to \$750.

### COLUMBIA MOTORS CUT

DETROIT, Aug. 8—The Columbia Motors Co., will reduce the prices of both the regular and Challenger lines, effective Aug. 15. Following are the old and new prices:

De Luxe touring, 5 pass., \$1,475, was \$1,795; sport model, 4 pass., \$1,475; roadster, 2 pass., \$1,475, was \$1,795; coupé, 4 pass., \$2,295, was \$2,495; sedan, 5 pass., \$2,350, was \$2,595; Challenger touring, 5 pass., \$1,195, was \$1,495; Challenger coupé, 4 pass., \$1,995; Challenger sedan, 5 pass., \$1,995.

The general specifications and standard manufactured units remain exactly as before in both the models, but refinements and changes in general appearance have been made in the bodies and the equipment has been changed slightly.

### WILLS CARS REDUCED

MARYSVILLE, MICH., Aug. 10—Having attained a sufficient volume of production, C. Harold Wills and associates have made a readjustment in retail prices effective Aug. 5 as follows: Roadster, \$2,785, was \$3,275; touring car, \$2,875, was \$3,275; coupé, \$3,750; sedan, \$4,100. No prices had been previously set on the enclosed models, as none have been in production. Work is well under way on these now, however, and deliveries are expected by September 1.

### RUBBER COMPANIES MERGE

ATLANTA, GA., Aug. 9—The Victory Rubber Mfg. Co. has been completely reorganized here, the organization including consolidation with the Cotton States Rubber Mfg. Co., and a general enlargement of the production of rubber products. G. J. Reuter is president of the new company, and also general manager. Other officers are S. S. Shepard, treasurer; Dr. W. P. Glover, A. L. Waldo and W. J. Burks, directors. The Victory company manufactures Seal-type tubes.

### DUESENBERG INFRINGES ON PATENTS IS CLAIM IN FRANCE

PARIS, July 28—Claiming an infringement of their patents on hydraulic 4-wheel brake systems, the Rolland-Pilain Co. of Tours made a descriptive seizure of one of the Duesenberg cars at Le Mans to-day. This action was taken, declared the Rolland-Pilain Co., in order to protect its legal rights in this system of braking. The seizure was merely of a technical character and does not tie up the cars or interfere with any of the arrangements made for shipping them back to America. Rolland-Pilain exhibited a hydraulic braking system at the Paris show in 1910, and although never having been in production intends to put his brakes on the market next year. The Duesenberg brakes are built under license obtained from an American company.

## Martin Parry to Open Seven New Branches

NEW YORK, Aug. 8—Seven new assembling and distributing branches will be opened in the near future by the Martin Parry Corp. They will be located in Philadelphia, Cleveland, Pittsburgh, Detroit, St. Louis, Kansas City and Newark. The same number of branches now are in operation. The purpose of opening the new stations is to carry a complete line of commercial bodies, relieving dealers from the necessity of tying up money in body stocks and to satisfy growing demands for sectional bodies. The plant of the company at York, Pa., is running at capacity and the Indianapolis plant on a 50 per cent basis. Sales for the first six months of the year were about \$2,300,000.

### FORD CUTS IN FRANCE

PARIS, Aug. 1 (By Mail)—Ford announces another cut in price for the French market. The touring model with electric lighting and starting is now sold at 12,150 francs, or without electric equipment 10,950 francs. These prices are for delivery at the Bordeaux assembly plant, and include the French luxury tax. Price of the chassis only is 8100 francs without electric equipment and 9350 francs with lighting and starting. The 1-ton Ford truck is listed at 10,375 francs, the 2-seater sedan at 17,275 francs, and the 3-seater sedan at 19,850 francs.

### MOLINE HAS FUNDING PLAN

CHICAGO, Aug. 10—The creditors' committee of the Moline Plow Co. reports that approximately 100 per cent of all outstanding obligations have been filed with it and that plans for funding the company's floating debt and the issuance of new securities to general creditors are assured of success.

## Expect Ternstedt to Produce at Capacity

**Body Hardware Makers Look for  
Busy Period After Taking  
Over New Plant**

DETROIT, Aug. 10—The Ternstedt Mfg. Co., through the acquisition of the England Mfg. Co. and the body hardware plants of the Fisher Body Co., now the largest manufacturer of automobile body hardware in the world, is going into production on a scale which it is estimated will carry it practically at capacity for the balance of the year. The company has been operating at capacity for 60 days, and President Paul W. Seiler declares orders on hand will carry it at full speed indefinitely.

Present business is running at 80 per cent closed body business, and Seiler looks for an increased closed body trade as the season advances. There is a decided trend, he said, toward the inclosed type of car for all-season use.

The company has just completed its new plant No. 2 and has finished moving in all equipment purchased from Fisher. The England factory will be continued as plant No. 3. The original Ternstedt plant continues as plant No. 1. With the completion of its factory arrangements the company is devoting its attention to standardizing body hardware.

Officers of the new organization are: Paul W. Seiler, former Ternstedt company general manager, president and general manager; C. P. Parsons, formerly president of the England company, vice-president; M. T. Boden, formerly auditor of Ternstedt, treasurer; C. R. Bitting, secretary; T. P. Archer, formerly superintendent of Ternstedt, factory manager; David Humphrey, sales manager, and F. M. Wardle, advertising manager.

## Hopes to Push Through Highway Legislation

WASHINGTON, Aug. 9—Senator Townsend, of Michigan, Chairman of the Senate Committee on Postoffice and Post-roads, is making a determined effort to dispose of highway legislation before the Congress votes a recess or adjournment. The committee will probably report by unanimous agreement a highway bill embodying the distinctive features of the so-called Townsend bill and a modified form of the Phipps-Dowell bill.

The Senate intends to provide for the establishment of a Federal Highway Commission—a principle which has the indorsement of the President and is advocated by the National Automobile Chamber of Commerce and affiliated organizations. While it is expected that some opposition will develop to the commission plan, belief is expressed that sufficient votes will be mustered to pass it.

## Franklin Company Has Pension Plan

Syracuse Manufacturers Decide  
on \$250 a Year as Minimum  
—Follows Much Study

SYRACUSE, Aug. 10—A pension plan whereby a minimum of \$250 a year will be paid employees as a reward of long and faithful service has been announced by the H. H. Franklin Mfg. Co., effective at once. The maximum is based on average earnings over a period of years.

The decision follows more than a year of study and investigation by H. C. Blagbrough, head of the industrial relations department, and George S. Dutcher, employment manager, during which they visited several large factories in the East which have adopted similar plans.

The plan is to be administered by a board of directors consisting of four company executives and the president of the mutual benefit society, which will be known as the annuities committee. It will run the plan absolutely, save that all decisions granting special annuities shall be subject to the approval of the executive committee of the company.

The plan provides for retirement on regular allowance after 20 years' service of male employees who have reached the age of 70, or women employees who have reached the age of 55, at their request; at 65 and 55, respectively, at their own request or without, at discretion of the annuities committee; after 10 years, if physical examination shows the employee to be totally incapacitated and incapacity is not covered by workmen's compensation laws, or whose retirement because of advancing years is deemed advisable.

Payments which may be authorized are 1½ per cent of the average pay for 10 years preceding retirement, but not less than \$250. Annuities will be paid monthly by check and their grant does not militate against a beneficiary entering other employment not prejudicial to the interests of the company.

## Grant Longer Credit to Midwest Engine

INDIANAPOLIS, Aug. 9—A two years' extension of credits, dating from June 27, which was asked the creditors of the Midwest Engine Co. because of the industrial depression which has made it difficult for the company to liquidate its inventory, has been granted, this representing more than 90 per cent of the face value of the claims. No change in the personnel of officers of the company is contemplated by this plan, but the creditors' committee, which is to be appointed and will consist of five men either creditors or representing creditors, is to co-operate in the company's management.

## Motor Cars New Rival for U. S. Railways, But— Trade Paid \$100,000,000 for Freight in 1920

NEW YORK, AUG. 8—The New York Times prints an editorial headed "Railways and Automobiles," which says:—

"It is announced that the Boston & Maine Railroad has abandoned two branch lines on account of automobile competition. So many preferred to ride in motor cars that the trains averaged only two or three passengers. The total freight revenue of one of the lines in 1920 was \$88. The other collected in 1920 \$1,713, with operating expenses of \$12,940. It was a case of short lines for summer travel. They never will be missed.

"The railways have no need of jealousy or fear of their rival, amazing though its growth has been. The automobile trade paid the railways \$100,000,000 for the year last reported. The automobiles of the farmers are feeders of the railways. They have expanded the area capable of economic cultivation, so that the railways get quantities of freight which never would have come into existence if the farmers still depended upon horses. It is difficult to place a limit on the growth of the industry which already has produced 11,000,000 machines. At the beginning of this year there was one car for each twelve of the population. The productive capacity of the country is a million cars more than enough to maintain the present total in operation."

## Result of Grand Prix Discussed in England

LONDON, July 29 (By Mail)—The sweeping victory of the Duesenberg cars in the French Grand Prix has caused considerable comment here. The outstanding facts are these:

(1) While Britain officially retired from the race, it is stated for lack of time to prepare and test the cars and the route, America took the risk and triumphed.

(2) The British cars which were raced as a private entry by the drivers, all credit to them, cut a sorry figure, due mostly to tire troubles, finishing at the tail of the list, whereas the American cars, though of single make and identical in detail, scored together closely.

(3) The press-men have not failed to note that the Duesenbergs are production, or commercially possible cars and not special cars impossible to build at the price the public will pay.

(4) The result of this victory effectively disposes of the delusion that American cars are inefficient from lack of European experience in design, etc. It now only remains for the Duesenberg Co. to disclose its European price for this car.

It should be added that many British spectators of the race have agreed that four wheel brakes were a big, if not the chief factor in helping the Duesenberg win, and it is agreed that such brakes will be indispensable in motor races. Other competitors were held back by the longer period taken for retarding and accelerating to the required pace.

### GUYOT'S TIME UNDECIDED

PARIS, Aug. 1 (By Mail)—In issuing the officially accepted times for the French Grand Prix race, the Contest Board reserves its decision regarding Albert Guyot's Duesenberg, placed sixth. On bursting a tire Guyot slipped into soft ground, and the claim is made that spectators helped to push him out. The rules of the race are that no outside assistance of any kind must be given the competitors.

## Say Trade Publicity Is Needed in Britain

LONDON, July 29 (By Mail)—A correspondent of *The Times Trade Supplement* this week discusses last week's overseas trade conference here. Points emphasized by this writer are:

Need for more effective trade propaganda abroad.

Need for a range of "comparatively rough" accessories of British make on standard lines.

Need for low and high powered motorcycles, large single cylinder engines excepted.

Need for air tired 3000 lb. capacity trucks, at lower prices than at present.

Need for vehicle makers to co-operate more with traders and parts-makers and to take more concern in such items as tires and other parts not made by themselves but essential to their products.

Need for larger and stouter tires on average British vehicles.

Reform in British auto taxation so as to enable a large cylinder bore to become normal for cars.

Virtually these recommendations and suggestions point to American ideals as to design, lay-out and mode of selling. The *Times* writer, however, seems to overlook the all essential fact that capital and co-operation among automobile makers are indispensable to any scheme involving a standardized product and adequate propaganda overseas, and it is just this factor which, while for years advocated and enlarged upon by competent critics, seems little nearer realization than ever.

Just now the main problem is finance which faces most British manufacturers.

### THIRD IN RACE MUST BE FRENCH

NEW YORK, Aug. 10—A cable dispatch from France says that as a result of American made automobiles winning the Grand Prix, the sporting committee of the Automobile Club of France has decided that in the race next year entries will be open to the world but that unless one-third of the cars entered are French, as well as one-third of the manufacturers represented, the club reserves the right to call off the race. The club feels that this puts the question squarely up to the French automobile makers who must provide the required proportion of French contestants if they want the race run.

## METAL MARKETS

**W**HILE a slowing up of the downward movement in prices is most decidedly in evidence, steel buyers are apparently convinced that they have nothing to lose by committing themselves for their more immediate requirements and to this sentiment is to be ascribed the impressive volume of business placed in the last ten days for immediate shipment. This condition holds especially true in the case of the sheet rolling mills which are working at approximately double the rate of operations in vogue in other branches of the steel industry. A considerable portion of sheet business for immediate shipment emanates from the automotive industries. That producers are eager to place their present ratio of operations on a more permanent basis is only natural and several are asking buyers to place orders for deferred deliveries, prices to be determined on the basis of the market at the time of shipment. Non-integrated sheet mills which cater to the automotive industries contend that bargains in sheet bars have disappeared from the semi-finished steel market and that on the present basis of \$32 for sheet bars they are unable to shade prices for full finished sheets further. All in all, the next week or two should reveal clearly whether the present buying movement is merely a flash in the pan or the beginning of a genuine resumption of lasting activity. As stated previously, steel makers are devoting considerable attention to measures designed to bring down freight rates. This movement now appears to have crystallized into more concrete form. Report has it that a conference of "Independents" is to be held in New York in the near future and that on that occasion energetic steps will be taken to secure a 20 per cent reduction in freight rates. Should this movement be fraught with success, consumers will undoubtedly derive a large share of the saving accruing therefrom. In the pig iron market conditions are becoming more and more settled from day to day and, as one large blast furnace representative puts it: "Bargain hunters are not having the picnic to-day that they did a few weeks ago."

**Pig Iron.**—Most of the sales to automotive foundries are for prompt shipment but some inquiries are out for deliveries over the third and fourth quarters. Some of the sales agencies and blast furnaces are disinclined to accept future business at present low quotations.

**Steel.**—Most of the buying of cold-drawn steel bars by the automotive industries continues in less than carload lots, although the leading low-priced passenger car builder recently took 800 tons of cold-drawn in a 3,000 ton lot of miscellaneous steel. Some makers quote 2.50c. which allows \$15 for conversion of 1.75c. hot-bars. The Corporation seems to be quoting 2.75c. but is protecting its regular customers by meeting the lowest quotation they can get from "Independents." Small tonnage buyers of strip steel are more numerous and automotive parts producers are placing orders for a few carloads at a time. As low as 4c. has been quoted on cold-rolled and 2.40c. on hot-rolled, although the general cold-rolled quotation given is 4.25c. with up to 2.60c. asked for hot-rolled.

**Aluminum.**—The "outside" aluminum market is demoralized. London cable state that, although the nominal quotation is 125 Pounds Sterling for export business, sales have been made at as low as 100 Pounds

Sterling f.o.b. At the present rate of exchange this latter figure is the equivalent of 16c. per lb. In 300 ton lots prompt shipment aluminum has been offered in this market at as low as 18c. per lb., duty paid, f.o.b. New York.

**Copper.**—Producers and speculative holders are seemingly willing to cut prices to the bone in order to obtain funds.

**Tin.**—The market is still feeble and correspondingly attractive to bargain hunting speculators.

## FINANCIAL NOTES

**Moline Iron Works, Moline, Ill.,** has increased its capital from \$500,000 to \$750,000. Reports on business for the past year made to stockholders at their annual meeting were gratifying and it was said the outlook for the coming year was favorable. The automobile accessories branch of the company has done a substantial business since it was established. L. E. Nutt continues as president of the company.

**Wright Aeronautical Corp.** directors have declared on initial dividend of 25 cents a share on the 224,390 shares of capital stock now outstanding. The report of the company for 1920 showed net earnings after all deductions of \$411,349, equal to \$1.88 a share on the stock. The gross sales were \$1,486,000.

**J. I. Case Threshing Machine Co.** reports that sales for the first seven months of 1921 have increased month by month and now amount to approximately \$10,500,000 which was 45% of 1920 sales, 54% of 1919 sales, 71% of 1918 sales and 143% of 1917 sales for the same period.

**Spicer Mfg. Co.** in a balance sheet as of December 31, 1920, shows cash amounting to \$455,425; inventories of \$6,292,263; accounts and notes receivable, \$1,810,633. Notes payable come to \$2,852,691, accounts payable \$867,047 and surplus \$2,007,846.

**American Bosch Magneto Corp.** showed an operating loss of between \$40,000 and \$50,000 for the half year ended June 30. The company owes only \$400,000 on current accounts against which there are \$5,700,000 of quick assets.

**H. H. Franklin Mfg. Co.** directors have approved issuance of \$2,500,000 additional 7% cumulative preferred stock of the \$15,000,000 authorized. This brings the total outstanding to \$6,636,600.

**McCord Mfg. Co.** has announced that 10% (\$450,000) of indebtedness to banks and creditors will be paid Aug. 11, together with \$150,000 interest, with money acquired from reduction of inventories.

**Goodyear Tire & Rubber Co.** has placed on sale the new issue of prior preference stock. The issuance of this stock marks the final steps in the Goodyear Company's \$85,000,000 refinancing program.

**The White Co.** has reduced bank loans \$2,500,000 since March 31. The company has been selling trucks faster than they have been produced since the price cuts a few weeks ago.

**Hendee Mfg. Co.** during July reduced its quick liabilities \$189,000 or from \$492,000, to \$303,000, of this reduction \$140,000 was in bank loans, which now stand at only \$100,000.

**Kohn Mfg. Co., Milwaukee,** manufacturing spark plugs, has filed schedule on a petition in bankruptcy, showing assets of \$47,554 and admitting liabilities of \$34,747.

**D. C. Willis,** chairman of the Fourth Federal Reserve District, announces that the district discount rate on all classes of paper has been cut from 6% to 5½%.

German Car Makers  
Gaining Foothold

## American Correspondent Describes Plan to Open Foreign Markets

**CHICAGO, Aug. 9—**There recently have come to the United States from many sources reports that German automobile manufacturers were gaining a strong foothold in various countries for passenger cars and trucks which can be manufactured more cheaply there than in the United States. Substantiating these reports, the following wireless dispatch has been sent to the *Chicago Daily News* by George Witte, its correspondent in Berlin:

"Scores of the Americans who constitute the vanguard of the army of travelers and who have invested from 200,000 to 400,000 marks, or \$3,000 to \$6,000, in German automobiles de luxe say that they could not possibly buy machines as good as these for twice the money in the United States. If these instances are an indication of what will happen as soon as Berlin is visited by as many Americans as before the war, then the automobile manufacturers in the United States will have to look out.

"To-day Germany has more than 100 automobile factories, employing 50,000 skilled workmen. All are turning out high grade cars, of which 75 per cent are solely for export purposes. There is no market in Europe or South America to-day for cheap cars. The German makers argue that people who can afford to run cars with gasoline at 50 cents a gallon want something showy for their money.

"In Magdeburg, the center of the automobile industry, the writer found the factories with enough orders on hand to keep them running for 18 months, and give them a financial basis for extensions on a large scale. Owing to the cheapness of labor, steel, iron and other materials, the factories are able to offer for sale handsome cars with good engines at from one-third to one-half the standard American prices. As a result, Germany already has taken the lead in the Swiss automobile market away from the United States. Last year Germany exported to Switzerland automobiles valued at about 18,000,000 Swiss francs (approximately \$3,600,000) while the United States exported to the same country only about 16,500,000 francs, (\$3,300,000) worth of motor cars. Altogether Germany exported 20,000 automobiles of various kinds and 4000 motorcycles in 1920, while in the last year before the war she exported 6400 cars and 2700 motorcycles."

## KAHN LIABILITIES \$34,747

**MILWAUKEE, WIS., Aug. 9—**The Kahn Mfg. Co., Milwaukee, makers of spark plugs, recently declared bankrupt, filed schedules admitting liabilities of \$34,747 and claiming assets of \$47,554.

## MEN OF THE INDUSTRY

Mason B. McLaughlin of Cleveland, who has been manager of the central sales department of the White Co. for a number of years, has been promoted to a vice-presidency of the corporation. The action was taken at a meeting of the board of directors held here last week. Robert A. Woodruff, manager of the southeastern department of the company, was also named a vice-president. McLaughlin and Woodruff, with vice-presidents James A. Harris and George F. Russell, will have headquarters at the general offices, from which they will direct sales all over the world. They are to compose a sales committee, a new body which has been established.

H. J. Edwards has resigned as manager of the Ellyria plant of the Willys-Overland Co., where all the engines for Willys-Knight cars have been made. Edwards is one of the pioneer designers of the automotive industry. He designed the Stoddard-Dayton car, and when it was taken over by the United States Motors Corp. went with that company. In 1911 he designed the Edwards-Knight engine and established a factory in New Jersey. His engine rights later were purchased by John N. Willys and the motor has been used in the Willys-Knight car. Edwards has been with Willys continuously since that time.

A. J. Banta for years manager of the Chicago branch of the Locomobile Co. and more recently manager of the Maxwell Sales Co. of Chicago has been appointed general manager of the Clydesdale Motor Truck Co. of Clyde, Ohio. He is familiar with both the sales and manufacturing end of the truck business having merchandised Riker trucks as Locomobile manager. He formerly was associated with the production department of Maxwell and prior to that was in charge of production at the Premier plant.

D. H. Roberts, sales manager of the Latex Tire & Rubber Co., Fond du Lac, Wis., resigned Aug. 1 to accept a similar position with the Sangamon Rubber Co., Springfield, Ill., which formerly was known as the Wilson Tire & Rubber Co. Mr. Roberts is succeeded in the Latex organization by Harry Benner, who was assistant sales manager.

W. R. McCulla has been appointed district manager of the Bjur Motor Appliance Co. with headquarters in Detroit. He has had a long record of engineering experience with the Packard Motor Car Co., the Willys-Overland Co. and other automobile manufacturers.

Harvey J. Mallory, controller of the Buick Motor Co. has been elected a vice president of the company but will continue as controller. He succeeds C. H. Mott recently made chairman of the advisory committee of the General Motors Corp.

Guy W. Vaughan, who has been with the Van Blerck Motor Co., Monroe, Mich., for two years as vice-president and general manager, has resigned as general manager, but remains as vice-president and a member of the board of directors.

B. Edwin Hutchinson, for four years treasurer of the American Writing Paper Co., Holyoke, Mass., has resigned to assume a similar position with the Maxwell Motor Co. and the Chalmers Motor Corp. in Detroit.

August J. Luedtke, secretary and treasurer of the Milwaukee Corrugating Co., a large metal working concern of Milwaukee, has been elected vice-president of the Concordia Fire Insurance Co., Milwaukee.

Vern E. Burnett has been appointed advertising manager of the Cadillac Motor Car Co. He recently resigned as advertising manager of the Liberty Motor Car Co.

H. N. Schwarze, electrical engineer for the Cadillac Motor Car Co., has resigned to join the engineering staff which is being organized by R. H. Collins.

T. J. Turk, who has been manager for the receivers of the Spacke Machine & Tool Co., Indianapolis, axle division, for the last year, has resigned.

A. B. Fletcher, state highway engineer of California, will be appointed director of the new department of public works.

## INDUSTRIAL NOTES

Westinghouse Electric & Mfg. Co., East Springfield, Mass., has added 200 men to the working force in the last two months. This month the firm will ship 7000 starting motors and lighting generators with ignition accessories in proportion, for automobiles.

Reynolds Spring Co., Jackson, Mich., has plans for the erection of a new building, 132 x 204, two story and a trackless trolley system running between the Ostego and Water street plants. July was the best month of the year for the company.

E. L. M. Tire & Rubber Co. of Racine, Wis., is now operating its new plant of about 20,000 sq. ft. It was organized several months ago with \$200,000 capital and absorbed the E-Z Rubber Mfg. Co. of Racine. E. L. McKim, heads the new concern.

Marathon Rubber Products Co., Wausau, Wis., which recently took over the entire property of the Burlock Rubber Co., has plans for a brick and steel factory addition, to be ready about September 1.

Hood Rubber Co. sales for the first six months of the year were nearly up to the total for the first half of 1919, though some \$5,000,000 behind the figures for the same period a year ago.

Jasper Tire & Rubber Co., Jasper, Ind., and all of its tire, fabric and rubber for the making of tires will be sold at a private sale soon by Louis Mehringer, receiver.

Rolls-Royce of America has just completed its 100th car. Production for the year is expected to be about 300. Some of the cars will be shipped to England.

Ford Motor Co., of Canada's plant which was closed Aug. 1 for inventory will reopen August 16.

Sills Has Chevrolet  
Branch in New England

BOSTON, Aug. 1—W. C. Sills, formerly sales manager of the Chevrolet Motor Co., today took over the entire property of the Chevrolet Motor Co. of New England. He has formed the Sills-Chevrolet Company and will act as distributor for the company in this territory. Included in his purchase is the retail sales and show rooms on Huntington Ave., the wholesale department at 100 Cunnington St., and the large service station in the Shoe and Leather Building at Cambridge. He is reorganizing the entire three departments and he will have with him some men who were identified with Chevrolet sales in other parts of the country.

## BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES by the Guaranty Trust Co., second largest bank in America.

Clearly there is a great amount of money seeking highly liquid forms of investment. Secretary Mellon announced that the subscriptions to the recent offering of \$300,000,000 of Treasury Certificates amounted to no less than \$1,030,000,000 of which \$524,000,000 came from the New York Federal Reserve District. A total of \$376,362,500 was allotted.

The vast amount of capital for short term investment caused the abnormal drop in call money rates to 3½ per cent in New York on August 4 and this rate, so far below the general market for time loans, together with the requirements of the crop moving season, have tended toward the withdrawal of funds from the call money market. As a result the tendency last week was slightly upward, the range being 4½ to 6 per cent against 3½ to 5½ per cent in the previous week.

The stagnation in stock exchange speculation made the demand for call money as small as was the supply of this class of money, and the week closed with a rate of 6 per cent. The demand for time money also continued light and the offerings were few, the rate ranging from 5½ per cent to 6 per cent for all maturities from 60 days to 6 months. A few loans with all industrial collateral were put through at a ¼ of 1 per cent above this range. Commercial paper rates for choice names and all maturities were quoted around 6 per cent, with a rate of 6¼ per cent for secondary names.

The statement of the position of the 12 Federal Reserve Banks on August 3 shows a decrease of bills on hand for the week of \$22,341,000 to \$1,647,579,000. Deposits in the member bank reserve account declined also by \$18,717,000, but as a consequence of an increase in Government and other deposits the total deposits of the system actually increased \$9,792,000 to \$1,705,066,000 on August 3. Note circulation declined less than \$1,000,000 to \$2,536,673,000 in contrast with a decrease of \$27,000,000 in the previous week.

## Gold Holdings Increase

Gold holdings on the other hand increased \$21,582,000 chiefly through the acquisition of imported gold. This is about the same increase as during the previous week. Gold holdings stood on August 3 at \$2,552,832,000, but a decline of \$3,035,000 in legal tender notes, silver, etc., brought the total reserves to \$2,703,843,000.

As a consequence of these changes the ratio of total reserves to deposit and Federal Reserve note liabilities combined advanced from 63.4 per cent on July 27 to 63.7 per cent on August 3, and the ratio of gold reserves to Federal Reserve notes in circulation, after setting aside 35 per cent against deposit liabilities, advanced from 82.4 per cent to 83.1 per cent.

# Calendar

## SHOWS

Sept. 5-10—Indianapolis, Automobile and Accessory Show in conjunction with Indiana State Fair conducted by Indianapolis Automobile Trade Association, John B. Orman, Mgr.

Sept. 28-Oct. 8—New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January—Chicago, Automobile Salon, Hotel Drake.

Jan. 7-13—New York, National Automobile Show, Madison Square Garden, Auspices of N.A.C.C.

Jan. 28-Feb. 2—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.

Sept. 9 to 17—Ottawa, Ont., Can.—Ottawa Motor Show.

Feb. 6 to 11—Winnipeg, Can., Automotive Equipment Show, Western Canadian Automotive Association.

## FOREIGN SHOWS

September—Buenos Aires, Argentina, Passenger Cars and Equipment, La Pabellon de las Rosas, Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery, Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Sept. 5, 1921—Constantinople, Traction trials under the direction of the Turkish Ministry of Agriculture.

Sept. 23-Oct. 2—Berlin, German National Automobile Show, Auspices of German Auto-

mobile Mfg. Ass'n and German Automobile Club.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.

November 7-14—Paris, Seventh International Exposition of Aerial Locomotion in the Grand Palais of the Champs Elysees, Held by the Chambre Syndicale des Industries Aeronautiques.

March, 1922—Santiago, Chili, Annual Automobile Show.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador, Automotive Section.

Sept. 1922—Rio de Janeiro, Brazil, Automobile exhib-

its in connection with the Brazilian Centenary Association Automobillista Brasileira.

## CONVENTIONS

Sept. 14-15-16—Detroit, Credit Convention Motor and Accessory Manufacturers Association.

Oct. 12-14—Chicago, Twenty-eighth Annual Convention National Implement & Vehicle Ass'n.

Nov. 22—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

## RACES

Labor Day—Uniontown, Pa., Autumn Classic.

## Annual Licenses Show Increases in England

LONDON, July 10 (By Mail)—Ministry of Transport statistics show that licenses were in force on May 31 for approximately 853,900 motor vehicles.

The most marked increase in that of "motor-hackneys" annual license, for which now number 64,000 compared with 40,500. The licenses for these vehicles in the second quarter of the year were 32,500 compared with 1200 in the first.

The horsepower class, which includes all private cars, shows an addition of 2000 annual licenses, while the quarterly licenses have increased from 14,000 in the first to 36,000 in the second quarter—an indication that a large number of cars were laid up until the summer as a means of saving the tax.

On May 31 licenses were in force for 226,000 private cars, compared with 185,700 in 1920, 370,000 motorcycles compared with 278,600, and 96,500 motor-hackneys compared with 71,400.

The amount of revenue collected from Jan. 1 to May 31 was £8,750,000.

## Toledo Tractor Makers Again Cited to Court

TOLEDO, Aug. 10—The Automotive Corp., manufacturers of tractors here, is involved in further legal entanglements here in the Federal Court, where Judge John M. Killits appointed Fordyce Belford, master in chancery to handle the case for an indefinite time. The matter of appointing a receiver is held under advisement by the court.

It is claimed that the company has violated the "blue sky" laws by selling its stock for \$25 a share when only \$14 cash ever got to the company treasury.

It is claimed also that salesmen for the promoters declared the company had contracts amounting to \$2,250,000 worth of tractors, while the petitioners aver that less than \$1,000 is deposited with contracts which total only a few thousand dollars.

The complainant also points out that the corporation took over the Cyclomobile Mfg. Co., which is nil and has no visible assets. A. H. Wyatt is president; William Hulin, secretary-treasurer; and John L. Larkin, vice-president. The company has a factory in operation here and has built a few tractors.

## Sterling Executive to Direct New Company

MILWAUKEE, WIS., Aug. 9—Executives of the Sterling Motor Truck Co. of Milwaukee appear as the principals in the incorporation of the Motors Acceptance Co. of Milwaukee, which has been organized with an authorized capitalization of \$200,000 to do a general trade and commercial acceptance business, handling automotive business especially. The incorporators are Frank Luick, secretary, and Oscar E. Held, treasurer, of the Sterling Company, and Victor L. Brown, 1428 First Wisconsin National Bank Building, Milwaukee, one of the founders and for many years president of the Sterling company, who retired from office about a year ago to engage in financing affairs.

## Form New Organization to Handle Bell Trucks

OTTUMWA, IOWA, Aug. 9—The Bell Truck Sales Corporation has been organized at Ottumwa, Iowa, to take over the sale of the output of the Iowa Motor Truck Co., manufacturers of the Bell truck.

The new company is headed by Paul T. Browning, who is well known in the automotive industry, having been connected with General Motors for several years in the Buick division. He has been more recently with Sheridan Motors. Jack Miller, who has been with the Iowa Motor Truck Co. as sales and advertising manager, is secretary and advertising manager of the new corporation.

## Former Goodyear Man Becomes Manufacturer

AKRON, Aug. 9—The Falor Mfg. Co., Inc., headed by Shelby A. Falor, a former Goodyear official, has started production in its new factory in South Akron and will continue on a production basis of about 400 automobile tubes daily. It is announced the company will specialize in the manufacture of automobile tubes. Falor was with Goodyear for over 20 years as director of the sales department. He developed the Goodyear field in motorcycle tires.

For the past three years he was a member of the Goodyear board of control. He resigned when the board of control was abolished under the new financial control of the company and when the office of comptroller was substituted for it by E. G. Wilmer, successor to F. A. Seiberling as president.

## Philippine Railways Seek Doom of the Motor Bus

SEATTLE, WASH., Aug. 10—A vigorous fight is being made by railroad interests in the Philippine Islands, led by the Manila Railroad Co., to eliminate the automobile stages from the passenger and freight-carrying business in the Islands. Legislation to place prohibitive fees on the stages is being sought from the legislature of the Islands.

Public opinion in the Islands, according to the latest newspapers received here, is back of the automobile interests. Facts and figures showing the great development of motor vehicle transportation in the United States are being used with telling effect.

If the government considers it just and fair to the public, to kill the auto truck lines merely to save the railroad why not carry the governmental interference with business still further and deny the garages the right to hire cars to persons desiring to go to any place to which a train might carry them? asks one Manila newspaper.

## The True Relation Between Wages and Unit Cost

The relation between labor rates, labor earnings; and labor costs is not generally understood. Decreased wages do not necessarily mean decreased unit costs. Here is a timely discussion of a problem vital to the manufacturer at this time.

By Harry Tipper

**M**UCH discussion has been going on in the papers concerning the so-called liquidation of labor, which is not a liquidation in any sense of the word, but a reduction in the operating cost.

It is evident from these discussions that the relation between labor rates and earnings, with the concomitant relation between labor rates and costs, is not thoroughly understood.

A great many of the discussions have presupposed that a 15 per cent reduction in the rate of labor employed would bring about a similar percentage in the reduction of cost and a similar percentage in the reduction of earnings.

An examination of the best available labor statistics makes it evident that the rise and fall of labor rates does not agree with the fluctuation of labor earnings. Neither labor earnings nor labor rates have had more than temporary reductions in the history of labor since the beginning of the factory system. Although the rates of pay have gone up more rapidly in times of prosperity and remained more stationary in times of depression, they have receded only very rarely and the recession has been comparatively small and very temporary in its character.

"During and after the war the labor rates rose very much faster than the average earnings of the

workers in the same trades. Similarly the earnings of the workers in those trades have not decreased in proportion to the rates, since there was a tendency to reduce the rates of pay following the depression. The cost of wages to the manufacturer in the cost of production increased more rapidly during the latter part of the war and afterward, and since the depression began the cost per unit of production has fallen more rapidly than the reduction in the rate. In some of the metal trades factories, for instance, during the rise in wages the rate increased for some occupations to an average of 110 per cent.

At the same time, the efficiency decreased on the average to about 80 per cent, so that the actual cost was increased by considerably more than the rate.

In the period after the peak of industrial prices wages in some factories were reduced 15 per cent and in some others 20 per cent, while the efficiency of the workers increased 24 per cent, bringing the cost of production down much below the actual reduction in the rate of pay.

Curiously enough, however, during the rise, the individual earnings of the workers did not increase as rapidly as the rate and the earnings have not decreased very much since the turn of prices downward.

From the worker's standpoint, his whole position is measured by his earnings over the period. The carpenter who works on an average in the New York district of about 180 days in the year, does not figure that he makes ten dollars a day at that rate, but that he makes so much a week for the year. In fact, he is making about six dollars a day available income. Similarly, the factory worker who moves from job to job from time to time, who makes money at times from overtime and loses it from short time, and so forth, figures that he can depend upon a certain sum per week for his budget, whether he argues it out in this financial fashion or not.

For the manufacturer, of course, the rate of pay is important only where it represents an absolute rate per piece.

In any other situation the rate of pay must be translated into cost per piece before it can be considered in arranging factory costs.

From the beginning of the industrial development, the increased pay of the worker has been met almost every time by an increase in the productivity of the worker, either through the introduction of more skillful equipment or through the better distribution of the labor itself.

We have no evidence from past experience which could lead us to hope that labor would be reduced materially in its price over any considerable length of time. The cost of the labor must be reduced by the increased efficiency and this cannot be done solely through machinery or the better distribution of labor. It must be done through an increase in the human efficiency. Measures that will induce the worker to put out more productive power in proportion to his pay will play an important part in the reduction of labor cost in the period we are now entering.

Most of the labor statistics published are of little value because they record changes in the rates only, changes in the general conditions of employment only. They do not take into account the changes in the cost per unit of production or the average of the worker's earnings. The first is the necessary calculation in considering the manufacturing cost and the second is the important consideration in figuring the relative buying power of the worker.

Merely to say that the buying power will be decreased because the rates of pay are decreased is absurd. The reduction in the average earnings will do that. Merely to say that the factory cost will be reduced because the rates of pay have been reduced is equally absurd.

In some factories where the reduction has been arbitrary and without any apparent reason, the efficiency of the workers has dropped in equal proportions, so that the cost remained about the same. I know one or two cases where the rates of pay were reduced, while the price of the product remained the same, and I know that in one of these cases it was the definite intention of the workers under those conditions to produce less in order to even up for the manufacturer's action. His labor costs were not reduced by the reduction in pay and any fancied advantage he secured was nullified by the action he took.

The usefulness of the general labor statistics, therefore, depends entirely upon the elements entering into them and the way in which they are analyzed in the attempt to secure a knowledge of the tendencies from them.

Analysis of the methods employed by the individual manufacturer will do much to illuminate the problem of lower factory costs per unit of production and will show the very slight relation that exists between the rate of pay and the production costs in various factories employing the same type of labor.

The factors that enter into the labor cost per unit of production include the human factors and their influence upon the fluctuations in efficiency.

The figures alone are indicative only of the general tendencies; they do not illustrate the possibilities. Average figures are only relatively important; they do not aid in the solution of the problem for the individual manufacturer, and no average can be of much service to him in meeting the competition that he must face in his particular field.

There is a tendency for these general statistics to influence the manufacturer in his own actions unduly, either because these statistics appear to justify his own position, or because they suggest a lack of parity between his methods and the general condition.

The variation in the individual problem is the important element in the improvement of labor efficiency and the reduction of the cost of production.

The study of the individual problem is the important study.

Reflex action of the market will show any disadvantage from which the manufacturer may be suffering in his cost per unit.

The only way that his problem can be solved is by the study of his individual case, the elements that enter into it, and the methods that may be applied properly to its improvement.

The general statistics quoted so frequently in present discussions of labor conditions should not be treated too seriously by the manufacturer in estimating the future probability.

There is nothing in past history to indicate that the worker has willingly come back to a less convenient state of living or to lower earnings and nothing has come out of the past which would indicate that rates of pay have materially decreased for any length of time.

Increase in the efficiency of the individual is the only sound basis for the reduction of labor cost and this increase may be produced partly by mechanical arrangements, partly by a better understanding of the human being. In this direction the manufacturer can safely experiment, for every improvement will tend to become permanent.

In the direction of lowering the costs by the reduction of rates, there is not much hope of anything but a temporary alleviation, and this hope may not be realized if the workers do not increase their efficiency comparatively with the rate.

IT is believed that the production of platinum in British Columbia will soon be greatly increased. Investigations conducted during a number of years have disclosed the fact that the Fraser River and adjacent territory constitute one of the principal platinum deposits of the world. A plant is being erected and it is expected that reduction work will be commenced this spring. It is believed that for 250 miles along the Fraser River and 150 miles on tributary streams 75 per cent of the black sand deposits can be dredged and concentrates to the extent of 8 pounds to 40 pounds per cubic yard of dirt obtained.

# Design Features Brought Into Relief by Grand Prix

The straight-side cord tire performed specially well in the famous road race this year, while the large number of curves in the course brought the four-wheel brakes into particular prominence. Low weight of American cars created very favorable impression upon European engineers.

By W. F. Bradley

THE recent Grand Prix race marked a revival of long-distance road racing in France, after the disastrous race in July, 1914, when Germany with its six-cylinder aviation engines won first, second and third. This race has re-established with the French populace the value of road racing in the testing of the design of all parts of the car. Murphy's victory averaging 78.1 m.p.h. for 321.78 miles or 15 minutes faster than the Ballot, which finished second, left no ground for disputing the fact that the best car won. This speed, compared with 65.5 m.p.h. in 1914, indicates that advancement has been made during the past 7 years, notwithstanding the fact that the German six-cylinder Mercedes aviation engine, which was victorious in 1914, was well ahead of its time in engineering development.

To-day's race has drawn attention to straight-side cord tires in a way that could not be accomplished in 12 months of ordinary propaganda. It was a distinct victory for this type of tire, notwithstanding the fact that Europe has been opposed to the straight-side construction. The race was a victory for four-wheel brakes in that the 10.7 mile circuit, which was covered thirty times, was full of curves. It was also a victory for light-weight construction in that the Duesenberg cars were the lightest of the thirteen competitors in the race, with the possible exception of a 2-litre Ballot.

A very favorable impression was created by the low weight of the Duesenberg cars, compared with the European machines, and the conclusion was drawn that American metallurgists have got ahead of their European rivals. The following weights, although official, are not entirely accurate, but are valuable from a comparison standpoint. The total weight was obtained by deducting the declared amount of oil, gas and water in the car. As no machine came near the 800 kilos minimum, it was not necessary to empty tanks. Weight on front and rear axles was taken without any serious attempt to ascertain the center of gravity.

Car	Driver	Front Axle	Rear Axle	Total Weight
Duesenberg	Murphy	1052	1065	2028
"	Guyot	1053	1102	2041
"	Boyer	1049	1018	2006
"	Dubonnet	1049	1036	2015
Ballot	DePalma	1035	1131	2072
"	Chassagne	1042	1153	2081
"	Wagner	1023	1168	2055
"	Goux*	873	952	1814
Darracq	Boillot	1036	1102	2132
"	Thomas	1047	1223	2052
Talbot	Guinness	1078	1289	2191
"	Segrave	1113	1228	2189

\*2 litre car. All other cars had 3-litre engines.

In all cases the tanks contained very little fuel. It will be noticed that the Duesenbergs were more heavily loaded on the front axle than any of the others, this being due to their unit construction of engine and gearbox, compared with separate construction on a 3-point suspended sub-frame for Ballot, Talbot and Darracq.

There is reason to believe that the lightest engines were the Talbot and the Darracqs, yet these cars were the heaviest of the group. In the frame members alone there was very much more weight than in the Duesenberg frames and less strength. The rear axle, too, was considerably heavier, and the very fine work done in the engine had not been carried out in all the details of the chassis, with the result that total weight was unnecessarily high.

Definite information regarding power output naturally was not given out. There is reason to believe that the Talbots and Darracqs got the highest power on the bench, but they did not have the same economical utilization of this power as their rivals. Duesenberg states that he reached the peak at 4200 r.p.m., which is the same figure as for Talbot-Darracq. For the Ballots the peak was 3600 r.p.m. For a course of this nature a four-speed gearbox would have been an advantage, but its absence did not prevent Duesenberg winning. As an offset, of course, he had low weight and the ability to run the engine at very high speeds for short periods.

## Ignition Performance

Ignition honors were equally divided. Delco equipped Duesenberg, Talbot and Darracq, and the Swiss Scintilla magneto was used on the Ballot cars. There were no ignition troubles, and plugs, which were K.L.G.'s for the Europeans and A.C.'s for the Americans, were equally satisfactory.

After arrival in France three of the Duesenberg cars were equipped with the French Claudel carbureter. Murphy decided to retain his Miller, which he had got into first-class condition, for although the Claudel seemed to be rather better on acceleration, he was not disposed to take the risk of a road accident during a final test on the day before the race. The trouble with the Claudels was sticking throttle barrels, occasioned by road dust. Chassagne foresaw this and fitted a very heavy recall spring. Wagner and De Palma had to fit extra springs during the race. This was not the fault of the drivers so much as of the firm, for Ballot did not encourage suggestions from his drivers, and Chassagne was in a position to get work done which could not be attempted by the others.

One of the right angle turns

A hair pin turn

All cars in the race used four-wheel brakes. The Duesenbergs were of the hydraulic type and proved exceedingly efficient. For the road it was decided to inclose the drums and the operating mechanism, this being essential on a highway, although not necessary on the track. With the exception of Ralph De Palma's car, the Ballots were fitted with a service brake designed by Engineer Henry. It made the work of the driver lighter and proved very satisfactory in the race. Ballot had smaller drums on the front than on the rear. After road tests the Duesenberg crew realized there was an advantage in this and got the same result by cutting away a portion of the brake shoes. The Talbots and Darracqs had equal braking surface front and rear. Metal brake linings were used on all cars. The only use of fabric lining was for the Ballot clutches. Duesenberg led the field in the matter of stream lining. The shape of the body, the colors, the position of the drivers and the tone of the exhaust, all tended to exaggerate the impression of speed conveyed by the American cars, compared with their European rivals. Some of this, of course, was accidental, but the general impression was excellent.

### Tires

Tires played a very important part in the race which was started at one minute intervals, and in pairs. The Oldfield cords used on the Duesenbergs proved to be not quite suitable for stony French roads. No rain had fallen in this part of France for three months and the neighborhood being naturally sandy, all the road dressing disappeared after an hour's running, leaving certain portions of the course thickly strewn with stones. These were very destructive to the Oldfield cords produced under Indianapolis track conditions.

The Italian Pirelli company had brought out a new straight side cord tire of 35 by 5, which was supplied exclusively to the Ballot team. This proved to be a good tire for these conditions, for when Chassagne went out after 17 laps his tires were in first class condition, and Ralph De Palma covered the entire distance without making a change. The American driver imitated the Duesenberg team by going away without a spare wheel. The Frenchmen refused to do this. Experiments had shown that it was quicker to drive on the rim, even if the burst took place just after the pits, than to change on the roadside and then stop again to pick up a spare wheel. This was the first time cars had raced in France without carrying a spare wheel.

Dunlop also produced a new straight side cord which was supplied to the two Talbot and the two Darracq cars. This tire gave such poor service that Oldfield straight side cords and Michelin clincher bead cords had to be used. While it is extremely doubtful if they could have won the race, the Talbots and the Darracqs

certainly would have finished in much better position had their tires been equal to the Pirellis. These cars started out with the new Dunlop cord straight side but some of these only stood up for two laps, and before the end of the race the cars were running on a combination of Dunlop and Oldfield straight sides and Michelin clincher bead cord.

The French motoring public attaches an immense amount of importance to the lessons learned in racing, and the theorist who now comes forth to prove the detrimental influence of circumferential weight will find it hard to get attention. There are no signs that anybody is preparing to profit by this demonstration, but the fact remains that this race has made the way easier for the introduction of the straight side by dissipating many of the prejudices which existed against it.

The French cars had decidedly better tires for this class of road and were handicapped over such a comparatively short distance as 322 miles.

American prestige has been enormously enhanced by Duesenberg's victory in France. The win was so fair, there was such an absence of the element of chance, that all open-minded spectators admit the best car won. Boyer's Duesenberg went out with a broken rod, but Chassagne's Ballot was eliminated with a broken axle. Jimmie Murphy was overheating when he finished, but this was due to a leaky radiator punctured by a flying stone. Guyot's Duesenberg had clutch trouble, but so had Wagner's Ballot.

### Race Preliminaries

Murphy got into his Duesenberg still suffering from his accident of a week before, when, owing to the seizure of the brakes, he overturned in the ditch. He was carrying Louis Inghibert, who had been scheduled to drive No. 4 Duesenberg. Both men were pinned under the car. Inghibert was taken to the hospital with four broken ribs, but although the French doctors declared that Murphy had no fractures, he suffered so much that he believed one rib had been broken. Nevertheless he started in the race well bandaged.

All the competition lay between the Duesenberg and the Ballot teams. In addition to these two a couple of Talbots and two French Darracq cars had been entered, also a Mathis of only 1500 cubic centimetres, or half the piston displacement allowed under the rules. The Talbots and the Darracqs were in an unprepared condition and had been re-entered twenty-four hours before the start, after having been withdrawn. The Mathis had been delayed by strikes and in addition was incapable of winning by reason of its small piston displacement.

Louis Wagner burned the fabric lining of the Ballot clutch on the initial lap and after losing a quarter of an hour in making repairs and being further delayed

by sticking throttles, he did not figure as a serious contender.

Ralph de Palma, looked upon by the public as the fastest of the Ballot quartet, did not seem to have all the speed that was expected of him, and admitted after the race that his car was five miles an hour slower than when he drove it in America. He also was delayed by sticking throttle barrels. This defect was overcome by fitting extra springs, but not until a certain amount of time had been lost on the turns.

De Palma and Joe Boyer tied for first place on the initial lap, the time being 8 min. 16 sec. for the 10.7 miles of the course. Chassagne and Murphy tied for second place in 8 min. 21 sec., and Guinness and Andre Boillot tied for fourth place in 8 min. 39 sec. Thomas, on the Darracq, had mechanical troubles on the first lap.

Murphy and Boyer in Duesenbergs tied for first place on the second lap, making the two circuits in 16 min. and 13 sec., with Chassagne and DePalma following in the Ballots.

After a couple of laps Jean Chassagne on Ballot proved that he was the fastest of the Frenchmen. He handled his Ballot in a wonderfully clever manner and after trailing Murphy and Boyer for six laps he got ahead of the Detroiters in the seventh and took the lead on the twelfth lap after Murphy had stopped for two rear tires and gas. The Frenchman held the leading position for the next six laps, but could not shake off either Murphy or Boyer and began to be threatened by Albert Guyot, who, after an indifferent start, began to climb rapidly.

The height of excitement was reached at this point, for it was evident that all the French hopes rested on

Tommy Murphy in his winning Duesenberg

Chassagne. De Palma had never been able to get better than fourth, Goux was handicapped by having a car with a piston displacement of only 2 litres, and Wagner had a lot of time to make up by reason of his clutch trouble at the start. While Boyer and Murphy were chasing Chassagne hard, the difference between the blue French and the white American cars always being less than a minute, Chassagne pulled into the pits with gasoline streaming from his tank, caused by the breaking of the rear axle when the Ballot skidded on one of the turns in an effort to avoid Dubonnet's Duesenberg. The fractured axle struck the gas tank. This accident was similar to the one which befell Thomas when driving in the Targa Florio race.

With Chassagne out Jimmie Murphy had the race in his hands and was never headed until he crossed the line a winner.

## British Discuss Overseas Motor Car Trade

**A**N overseas automotive trade conference, promoted by a monthly automobile export paper, was held recently in London. The Government was represented by the new Minister of Overseas Trade who, while deploring the failure to stem the flood of imported automobiles despite the tariff of 33½ per cent on cars, had to explain the decision of the Government to cut down his own department to fit in with the country's present reduced spending capacity.

This Minister, however, was constructive and useful in suggesting the manufacture of a purely utility form of car for the Dominions.

The chairman of a truck company and a notable office bearer in the British trade's council indorsed the appeal to his fellow manufacturers to combine to produce the required car and urged that the overseas market could not be recovered unless wages were reduced and production increased. Ford has proved that there is a relation as of cause and effect between high wages and big output provided that the business is handled rightly and that those at the top of the enterprise concerned will reverse the British way of looking at things, namely, produce to create a demand, and not wait for the demand before starting to produce. This speaker, being a strong tariff man, deplored the Australian Government's recent decision to cut down the British preferential tariff to 5 per cent. Why not meet the situation with a combination of British automobile capital and set up a factory in the Dominions the same as other British industries have done recently, sending out their own picked staffs to develop the business?

Major Goddard, editor of the trade monthly which promoted the meeting, threw out several suggestions to the overseas visitors. In effect he asked the visitors to state "whether it was practicable to produce a type of car at a proper price for overseas trade; how best to push British cars and whether standardized component parts from which overseas traders could build their own cars would be of value?" Major Goddard, as might be expected from this quest for information, holds that the British automobile makers have failed in propaganda.

The visitor spokesmen told a few home truths to the effect that American cars are not the "duds" in the Dominions which interested parties would have us believe; that they wear reasonably well, and can be sold at the right price and that the business is effectively handled.

Ultimately it was resolved to convene a conference of overseas delegates to consider, first, problems of gearing; second, of adequate cooling, and, thirdly, of screening and hoods, as in these matters it was unanimously agreed by the overseas delegates that the American car was superior to the British.

**T**HE Stahlwerke Lindenberg A. G. of Germany have patented a new tool steel which, despite its relative softness, is claimed to allow of high cutting speed, to produce a smoother surface, to have a higher elastic limit and to require less lubrication than standard tool steels. These favorable properties are obtained by the addition of small quantities of refining metals, such as 0.3 to 1 per cent of chromium.

# Technical Features of New Durant Car

This new car, built along conventional lines, is likely to be a big commercial factor in the low-priced market. The engine is an overhead valve type, and the cylinders and top half of crankcase are in a single casting. Muffler construction adds materially to stiffness of the frame.

By P. M. Heldt

**T**HE new car of the Durant Motors Corp., which is being assembled at the former service station of the Ford Motor Co. in Long Island City, owes its importance mainly to Mr. Durant's standing in the industry. It will be turned out in large numbers and will undoubtedly be a big factor in the low priced market during the next few years.

The design throughout is along conventional lines for cars of the price class to which this model belongs, but the chassis is exceptionally "clean." The engine, which has cylinder dimensions of  $3\frac{7}{8} \times 4\frac{1}{4}$  in., corresponding to a piston displacement of a trifle over 200 cu. in., is of the overhead valve type. Cylinders and top half of crankcase are in a single casting, but the cylinder head is cast separately, so the valves can have their seats directly on water-cooled surfaces. The valves are located in a line extending the length of the engine and are operated through tappet levers in the usual way. The arms of the levers are of unequal length so as to give a slightly greater lift to the valves than the stroke of the tappet rods.

The waterjackets extend all the way down the cylinder barrels, and there is no offset in the casting at the lower end of the piston stroke. The tappet rods extending down the right hand side of the cylinder block are enclosed by a sheet metal cover, and there is another cover of pressed steel over the tappet levers and other mechanism on top of the engine. The latter cover is supported by means of risers cast on the cylinder head which also carry the shaft forming the pivot for the tappet levers. The cylinder head is held to the cylinder block by eight studs, of which the four on one side also hold in place the caps over the tappet lever pivot shaft. With valves in the head, the head cast-

ing is naturally much stiffer than one for an L-head engine, and a smaller number of bolts suffice to secure a gas-tight joint and hold the gasket securely.

The pistons are iron castings with three rings above the piston pin. The piston pin is clamped tight in the connecting rod and its ends bear directly on the cast iron of the piston bosses. There is nothing out of the ordinary in the design of the connecting rods, which are I-section drop forgings and have their caps held on by two bolts each, duly secured by cotter pins. Piston and connecting rod together can be removed through the bottom of the engine after the oil pan is taken off. The crankshaft has three main bearings and is of light design. The caps under the two end bearings are cast with segmental flanges with which the crankcase bottom half makes an oil-tight joint. This bottom half is a steel drawing and has the splash troughs riveted in it. The engine has a four-point support on cross members of the frame. Camshaft drive is through helical gears at the forward end, the housing being closed by a sheet metal cover.

Fuel is carried in a 13.5 gallon tank mounted at the rear of the frame, from which it is fed to the carburetor by a Stewart vacuum feed tank which is supported alongside the engine. The make of the carburetor has not been finally decided upon, but the car from which these notes were taken was fitted with a Tillotson. A rather novel combination inlet and exhaust manifold is used, the shape of which is clearly shown by the sketch herewith. The carburetor is located toward the rear of the engine on the right hand side.

The electrical equipment is of Autolite make. The starter is located on the left hand side and drives to a gear

Left side of engine, showing mounting of steering post, starter and horn

Right side of engine, showing manifold and mounting of vacuum tank

Triangular drive of pump and fan

Muffler mounted so as to reinforce frame against weaving

ring cut on the flywheel through an inboard Bendix drive. It may here be pointed out that the gearcase is a separate unit and the flywheel, starter and drive are uncovered, so that both the starter and its driving mechanism are in plain view on the chassis and very accessible. The generator is mounted on the opposite side of the engine, forward, and is driven from the camshaft through enclosed gearing. The same as the starter, the generator has a square sectioned field frame, and on top of it is mounted the ignition coil. The timer-distributor is also mounted on the generator, being arranged vertically in the usual manner. The high tension cables from it to the spark plugs are carried through a metal tube around the forward end of the cylinder block. All other wiring is encased in flexible metallic tubing.

Lubrication is by the circulating splash system, a gear type of pump being carried on the outside of the crankcase on the right hand side and driven from the generator through a flexible coupling. Oil is fed to the main crankshaft and to the camshaft bearings directly, and a pressure gage is mounted on the instrument board to indicate the pressure at which oil is delivered to these bearings. Oil is also delivered into each of the four splash troughs and into the cam gear housing, and splash within the case provides lubricant to all the other bearing surfaces. The oil pump draws its oil from a large strainer at the lowest part of the oil pan. There is a combined breather and oil filler on the right hand side of the crankcase near the rear, which is carried up sufficiently high to make it easy to renew the oil supply. The oil passages to bearings are drilled and there is no outside piping.

Cooling is by pump circulation. A centrifugal type of pump is mounted on the right hand side and is driven by a Vee belt from the forward end of the crankshaft. The same belt drives the four-bladed radiator fan, the drive being a triangular one, with one side substantially vertical. There is one peculiarity to the water pump, and that is that its impeller is located partly within the engine water jacket and its housing is of substantially semi-cylindrical form. This brings the pump drive shaft very close to the cylinder block and ensures free circulation of the water by thermo-siphon action in case of failure of the pump or its drive. As a means for adjusting the tension of the drive belt, the base of the fan bracket is provided with elongated holes by which it is bolted to the cylinder block. The hub of the fan contains an oil reservoir from which its bearings are lubricated. The radiator is of standard form and has a cap covered with a molded heat-insulating composition.

The muffler, which is located just inside the right hand frame side bar, between a cross member directly in front of the gearset and another substantially over the rear axle, serves the additional purpose of stiffening the frame against weaving. The frame is made up of  $4\frac{1}{2}$  in. channel sections with few cross members, of which two at least are quite flat, so that as a whole it is very flexible. The muffler, however, being a long tube of about 6 in. diameter and relatively heavy walls, and securely fastened to the cross members by means of flanges at both ends, adds greatly to the stiffness of the frame. The muffling elements are of the simplest possible nature. The exhaust pipe enters the muffler centrally at one end and is carried part-way through it. Its end is closed up but that part of the pipe within the muffler is perforated and the exhaust gas escapes through these perforations into the muffler, from which it passes to the atmosphere through an opening on the lower side of the rear end, formed by a bulge in the head.

The clutch is built together with the flywheel and is of the single plate type. The steel driven plate is slotted radially so as to prevent distortion through heating, and consequent trouble. On both sides of the steel driven disk there are floating disks of wire asbestos  $11\frac{1}{2}$  in. in diameter and on the outside of these floating disks are the flywheel web and a plate which is in direct driving connection with the flywheel. The disks are pressed together by a series of coiled springs located near the periphery, while the disengaging pressure is transmitted through a series of four levers, which, instead of being arranged radially to the clutch axis, are offset from that axis to such an extent that they pass the clutch shaft, which permits of a greater multiplication of the pressure. Except for the disengaging pressure multiplying levers, the clutch is completely enclosed. There is a large oil chamber in the shifting collar, and lubrication of the clutch bearing needs to be attended to only once a year.

Between the clutch and the gearset there is a short intermediate shaft with two fabric universal joints, the spiders of which have two arms each. The gearset is supported on a cross member of the frame. It is of the ordinary three speed and reverse, selective sliding type and is fitted with annular ball bearings on its primary shaft. The shifting lever is of the ball-mounted, ball-handled type and is centrally located. Gear positions are arranged in accordance with S. A. E. recommended practice. The emergency brake lever is mounted on the right side of the gearbox and operates on a toothed sector as usual. Cast iron is the material of the gearcase. The latter is of the

Central part of chassis

functional form, the walls coming close to the contained parts at all points, and is therefore exceedingly compact. The speedometer drive is taken from the rear end of the gearset.

Between the gearset and the rear axle is inserted the solid propeller shaft with two metal type universal joints. The final drive is by spiral bevel gears and gives a reduction ratio of  $4\frac{1}{3}$  to 1. Ring gear and pinion are of chrome nickel steel, the former being fastened to the flange on the differential by riveting. The rear axle is of the built-up, three-quarter-floating type. At the differential there are annular ball bearings and at the wheels Timken roller bearings. The differential is of the two-pinion type. As usual with the built-up housing, the axle carries an under-running truss.

The frame, as already mentioned, consists of  $4\frac{1}{2}$  in. channel bars, and these are straight from end to end in the vertical plane, but are set considerably farther apart at the rear than at the front. The frame is supported by half-elliptic springs all around, the rear springs being 48 in. long and the front springs 34, and both sets 2 in. wide. The rear springs are underslung. The Alemite lubricating system is used for the whole of the chassis. All shackle bolts are hardened and ground. Torque reaction and driving thrust are taken care of by a Hotchkiss drive.

In connection with the frame, mention should be made of the method of supporting the storage battery. The latter is located alongside of the gearset. A shelf in the form of a steel plate is riveted to the underside of a frame cross member on which the battery is set. A steel band passes horizontally around the battery at about mid-height, its ends being provided with pull-up screws which extend through the web of the cross member and are drawn up by nuts, thus holding the battery firmly in position.

The front axle is of the regular I-beam type, but the steering knuckles are of the inverted Elliot type which is found more frequently in cars of the higher priced class. Stops are forged on the knuckles to limit the steering deflection and prevent contact between the tires and parts of the chassis. The tie rod is located to the rear of the axle in a protected position. The drag link extends crosswise of the chassis and connects to a separate ball stud. Two Timken roller bearings are fitted in each front wheel. A feature of apparently considerable importance from the driver's point of view is that each wheel hub is formed with an extension in which a central screw thread is tapped, so that by carrying along a bolt of quite moderate dimensions the driver always has a wheel puller with him.

The steering gear is of the worm and complete wheel type and the post is strongly raked. The steering gear housing is located between the engine crankcase and the

frame directly to the rear of the frame cross member supporting the front end of the engine. Back of the steering gear housing is located the vibrator type of electric horn and back of this the starter. Beneath these parts there is a sheet steel filler plate extending between the engine and the frame. These accessories all lie quite low down, and the sides of the engine higher up are encumbered very little.

The steering wheel is 16 in. in diameter and has a walnut rim and an aluminum center. The inner ends of the spokes show as aluminum and the outer ends as wood, giving an attractive appearance. Spark and throttle controls are of the aluminum die-cast type, held in position by friction, and are mounted centrally on the steering post. The horn button is also located on top of the steering post. From the lower end of the steering post the connections to the carburetor and ignition unit are by flexible steel wires extending through tubes with their ends fixed, after the manner of Bowden wire controls.

Both sets of brakes act on drums on the rear wheels. The outside brakes are the service brakes and the inside the emergency. The brake drums are 12 in. in diameter; the inside bands are  $1\frac{3}{4}$  in. wide and the outside 2 in. Each set is provided with means of adjustment adjacent to the drum which can be operated without the use of tools. The cross shaft for the brake linkage is located in front of the gearset, being supported by the same frame cross member which carries the transmission and storage battery. For supporting the clutch and service brake pedals there is a small sub frame, that is, a pair of short channel section frame members extending longitudinally.

A somewhat novel form of hood catch is used. This consists of a T-fitting, the shank of which extends through an

opening in the hood, and is provided at its lower end with saw tooth slots on opposite sides, while the spaces in between are left smooth. Secured to the frame side members are catches of hardened steel which engage into the slots on the shank of the T-fittings when the catch is locked. When the driver wants to open the catch he slightly

presses down on the T-fittings and then turns them around their axis through a quarter circle, whereupon they may be pulled out. The sketch herewith illustrates the idea fully.

The construction throughout is quite light and the five-passenger touring car, we are informed, weighs only 2300 lbs. The bodies are upholstered in leather and the tops are made of a leather substitute and provided with a glass window in the back. The cars which the writer inspected at the Long Island plant had a well balanced and well finished appearance. Tire equipment is 34 x 4 in. Goodyear on wood wheels with steel fellos. A very rigid tire carrier is mounted at the rear of the body. The equipment includes drum shaped headlights with non-glare lenses; dash light, tail light and license holder on rear tire carrier, electric horn, speedometer, demountable rims with extra rim, ignition lock, robe rail, Alemite pump and a set of tools.

# New Model Light Cars Planned by British Makers

The success of the low powered, light weight car Rover is causing well known firms to enter this competition. Exhibitors at last Olympia show express dissatisfaction with the two building arrangement and some threaten to withdraw.

By M. W. Bourdon

**I**F present plans mature, the next Olympia show will see several firms well known in the world motor industry showing supplementary models which will be striking departures from their present output.

Rolls Royce, for example, has a 20 hp. six-cylinder on the stocks, but no details are yet available;

Daimler is planning a 12 hp. four-cylinder at a popular price;

A company associated with the Daimler, the Birmingham Small Arms Company (B. S. A.) now selling motor cycles only on the automobile side, has taken up a two-cylinder air-cooled Vee engine which Hotchkiss has been testing out and will make a runabout to compete with the highly popular 8 hp. Rover and cut across the elaborate motor cycle and side-car outfits in price and performance.

Armstrong-Siddeley has a 10 hp. water-cooled light car in prospect;

Singers, who have bought up the Coventry Premier, are making a four-wheeler under the last name also to compete with the little Rover.

The success of the Rover, both from the practical and the sales standpoints, will, in fact, result in its having several serious competitors next year with the reputations of well-established firms behind them, while the existing light car makers will also find competition increased by additions to their numbers.

The Star Co., for instance, has recently announced a new model of this type with a four-cylinder engine 69 x 120 mm. (2¾ in. x 4¾ in.) for two and four-seated bodywork and selling at £495 and £545 respectively (say \$2500 and \$2750 at normal rate of exchange.)

## London Show Space

**A**S a result of the dissatisfaction which was loudly expressed by those exhibitors at the 1920 London Show, who were relegated to the White City buildings instead of being accommodated at Olympia, a deputation waited upon the Council of the Society of Motor Manufacturers with a protest concerning the method in which the ballot for positions has in the past been conducted. They wanted all exhibitors to be given equal chances of getting into Olympia or else an assurance that some at least of the most widely known firms should accompany them to White City.

It has been felt that the public looked upon the White City section as a "side show" where only new and unimportant firms were to be found, and as stated in *AUTOMOTIVE INDUSTRIES* at the time of the last show, this was undoubtedly the view taken by a large proportion of the public. The majority of American cars were at White City, though there were many at Olympia

as well; the former were mostly newcomers to the British market and they certainly were not exhibited to the best advantage in being unable to have space at Olympia.

But the S. M. M. T. has decided that existing ballot arrangements must hold, despite the threat of complete abstention from the show on the part of the deputies and those they represented failing acquiescence with their request. To enable the matter to be further considered by the dissatisfied firms it was decided by the Council to postpone for a week the closing date for applications for space. Incidentally it was mentioned to the deputation that the attendance last year at White City was approximately 70 per cent of that at Olympia, but if the writer's opinion is justified it was the other 80 per cent that included the majority of potential buyers; they went to Olympia first, from habit if not through ignorance of the existence of the other section and Olympia got most of their orders.

This division of the show is a very poor makeshift for a one-building exhibition, and there is an increasing demand for a complete withdrawal from Olympia and a concentration at White City; the latter would accommodate all comers. But the S. M. M. T. Council consists mainly of representatives of firms entitled to participate in the initial ballots for space and naturally they are not keen to give up the advantage they hold under the existing arrangements.

## Motor Tractors in French Railway Service

**E**XTENSIVE use of motor tractors in the distribution of freight is being made by the Orleans railroad in France. Tractors of 3100 lb. weight are used, which are strongly built only in the frame, but as regards the engine power are about equal to ordinary passenger cars. The tractors are fitted in front with single and in the rear with dual pneumatic tires, and carry over the rear axle a vertical screw spindle which serves to press down the tongue of the trailer, so that part of the trailer load can be transferred to the axle of the tractor. This makes it possible to haul with so light a tractor trailers which carry up to 8 tons useful load. The trailers themselves run on solid rubber tires. Originally the railroad provided two trailers for each tractor, while in addition one tractor served for switching purposes in the yard. Later the number of trailers was increased to three. According to the experience so far had, one driver can make four trips daily with 18 to 20 tons of freight and a mileage of 28, which is equivalent to the work of two teams. The company plans to install a total of 20 tractors and 50 trailers at the Ivry Depot in Paris.

# A New Block-Cast Six-Cylinder Engine

Overhead valves are operated by rocker arms and push rods from camshaft in crankcase. Constant clearance aluminum pistons employed. Engine is characterized by unusually neat external appearance. Weight is 600 lbs.

By J. Edward Schipper

**T**HE Rochester engine is an interesting combination of racing and commercial practice. It differs materially from the Rochester-Duesenberg four, described in *AUTOMOTIVE INDUSTRIES* for March 4, 1920. An overhead valve with overhead rocker arm action is used in place of the long side rocker arm employed for the racing engine and the four-cylinder type previously described.

The Rochester six-cylinder engine employs two valves per cylinder. It is a block-cast unit with detachable head in which the valves are carried. The crankcase is of conventional type, the upper half carrying the main bearings. Aviation practice has been followed in one particular for the main bearing studs run completely through the case and hold down the cylinders.

The cylinders have a 3.6 in. bore and the stroke is 5 in. A maximum of 80 b.h.p. is developed at 2600 r.p.m. The cylinder casting is of semi-steel and is noteworthy for its clean exterior. On the right side of the block there is nothing except the water outlet and the valve adjustment cover plate. To the left side of the engine are bolted

the exhaust manifold and the carbureter, which latter is of a horizontal type, the intake manifold being integral with the cast iron cylinder head.

The pistons are aluminum alloy of the constant clearance type. In this piston, the head is partly separated from the skirt by means of a slot which compensates for the normal expansion of the metal. The pistons are of the flat head type and are equipped with three rings all above the piston pin. The piston pin is of seamless steel tubing, hardened and ground. The pin floats in the piston, and is clamped in the end of the connecting rod. The piston assembly weighs 1 lb. 4 oz. The clearance of the piston skirt is 0.004 in. and the clearance over the ends of the piston pin is 0.025 in.

The connecting rods are I-beam section and weigh 3 lb. The lower rod bearing is a bronze backed, babbitt lined type, the cap being retained by two nickel steel bolts. The crankshaft is a three-bearing type, drop forged from 40-50 point carbon steel. The shaft is of the inherently balanced type with bow shaped throws. The main bearings are babbitt

View of Rochester engine with bottom pan removed showing crankcase and crankshaft bearings

Right side of Rochester, six-cylinder, block-cast engine showing water pump, generator and magneto drive

Left side of Rochester engine showing exhaust manifold which has its outlet forward. The intake manifold is integral with cylinder head

lined and bronze backed. The bearing sizes are  $2\frac{1}{4}$  in. diameter throughout, the lengths being 2.5 in. for the front and center bearings and 3.5 in. for the rear bearing. The flywheel is a steel forging.

The valve actuating mechanism consists of a train of three gears, these being connected with the crankshaft, water pump and camshaft respectively. The camshaft and water pump drive gears are of 40-50 point carbon steel, whereas the camshaft gear is of Bakelite. These are helical gears and they are housed in the usual manner in the front end of the crankcase. The three-bearing camshaft is located within the crankcase. Besides the integral cams it carries a helical gear for the oil pump. The camshaft is pack-hardened and ground. The cam followers are of 35-45 point carbon steel, of the mushroom type, operating in cast iron guides bolted to the cylinder blocks and detachable in groups of six. The push rods are of seamless steel tubing, with ball and socket ends. The upper end of the push rod is socketed to receive the ball on the end of the rocker arm. The rocker arms are also of 40-50 point carbon steel, with a hardened button which bears on the end of the valve stem. The other end of the rocker arm is drilled and fitted with an adjustable tappet bolt, the lower end of which rides in the push rod socket, as described. This tappet bolt is secured in position by a lock nut, and movement of the bolt provides adjustment on the valve drive. The rocker shaft bearings are bronze bushed, the shaft being of steel tubing secured in three brackets in the cylinder head.

Transverse section through  
Rochester six-cylinder overhead  
valve engine

The valves are of  $1\frac{9}{16}$  in. clear diameter with  $\frac{3}{8}$  in. lift. The inlet valves are of nickel steel and the exhaust valves of tungsten steel. There are two coil springs to each valve. Over the valve mechanism is an aluminum alloy cover bolted to the cylinder head with three center studs.

Lubrication of the engine is by a full force speed system. The oil is pumped by a gear driven pump operated from the camshaft by helical gears. The entire pump can be removed as a unit from the base of the engine for cleaning. Oil is forced to the main bearings and connecting rod bearings, as well as to the camshaft and rocker arms. Overflow from a relief valve lubricates the water pump shaft and timing gears. The pistons, piston pins and cam followers are oiled by spray.

Water circulation is effected by a gear driven, centrifugal water pump. The fan pulley is located on the forward end of the pump shaft, which also takes care of the generator, and distributor or magneto drive. The fan is a four-blade, aluminum casting, of the propeller type. Either battery or magneto ignition can be employed with the engine. When magneto ignition is used, the magneto is mounted on a bracket to the rear of the generator and driven through the pump and generator shaft. When battery ignition is used, the distributor is driven by a vertical shaft just to the rear of the timing gear case. The bracket for

the magneto and generator are cast on the crankcase.

The engine is provided with standard S. A. E. bosses throughout. Its weight is 600 lb. It is manufactured by the Rochester Motors Corporation.

## Cooling Surface Requirements of Airplane Engines

**F**LIGHT tests were recently made at McCook Field, Dayton, Ohio, on a Fokker D-VII equipped with a 200-hp. Mercedes engine to determine the effectiveness of the cooling system. It was found that during climb the system operated on a temperature difference of 71 deg. C., which will insure against boiling with a normal air temperature gradient and 75 deg. F. ground temperature. This is 16 per cent cooling capacity less than U. S. Air Service requirements, and is characteristic of European planes. Cooling requirements in Europe are not as severe as those in the United States.

The shape and position of the radiator are advantages from the standpoint of installation and clean design, although effectiveness of cooling surface is somewhat decreased at the sides by the slanting core face. It is not a very satisfactory radiator for production, owing to the use of tubes of several different lengths. The shutter is unsatisfactory, giving poor control, owing chiefly to its failure to tightly cover the air passages through the radiator core and it being in the rear of same.

The over-all dimensions of the radiator were 28 in. in width, 25 in. in height and 12 in. in depth, and the

weight was 48 lb., empty. The frontal area in the direction of travel was 1.45 sq. ft.; the cooling surface, 126 sq. ft.; the outside diameter of the core tubes 0.250 in. and the thickness of the walls, 0.007 in.

Curves published in connection with the report show that the circulation was at the rate of 70 gal. per min. for a corrected pump pressure of 2 lb. per sq. in.; 98 gal. per min. for 3 lb. per sq. in. and 132 gal. per min. for 5 lbs. per sq. in. The cooling system reached a maximum temperature between 3000 and 4000 ft. altitude, the jacket inlet temperature then being 70 deg. C. and the outlet temperature 76 deg. C., which gives a water temperature gradient of only 6 deg. C. or 11 deg. F.

**T**HE final report of the Chief of Air Service A. E. F. to the Commander-in-Chief, American Expeditionary Forces is printed in No. 180 of the Air Service Information Circular, dated Feb. 15, 1921. It contains an account of all the activities of the Air Service from the time the United States entered the war to the signing of the Armistice, with numerous tables and diagrams. Concerning the Liberty engine it is said that "in actual service it fulfilled the highest hopes of it which had been entertained."

# An Analysis of the Automatic Ignition Advance Mechanism

Desirable rate of advance is for most engines a direct function of speed, but since centrifugal force increases as square of speed a compensating mechanism, the design of which is here outlined, is required.

By C. H. Hindl

ONE of the advantages of electric ignition is the ease and accuracy with which the spark can be timed. It is the purpose of the following paragraphs to deal chiefly with the method by which the spark timing is automatically controlled.

The point where ignition occurs is of considerable importance in the operation of the engine. Although the phenomenon of combustion is not clear in some of its details, it is a well-known fact that a considerable interval of time passes between the periods in which ignition occurs and in which the combustion of the mixture is complete. This period is usually spoken of as time required for the flame to propagate to various parts of the cylinder. In addition to the time required for the combustion of the mixture, there is an additional interval of time before any pressure is obtained in the cylinder. In other words, the flame travels part way through the combustion chamber before any pressure is registered on the piston. Since it is desired to utilize this pressure during the power stroke and have complete combustion before the end of the stroke is reached, it is necessary to carefully regulate the time when ignition occurs with respect to the piston position.

In the early days of the automobile, drivers were more or less skilled in the operation of the engine and controlled the spark advance by hand according to the "feel" of the engine. However, the use of the automobile has increased to the extent that the driver in most cases is not familiar enough with the engine operation to adjust the spark to the position for best engine efficiency. As a result, the engine may run hot and lose power on account of the spark being too far retarded or the spark may be advanced excessively, causing loss of power and knocking. Another serious disadvantage of hand control becomes effective when the engine is started, as the spark may have been advanced to a degree that will cause backfiring, which might seriously damage the starting motor and its mechanism, while with automatic advance the spark is always retarded at cranking speeds so that backfiring cannot occur.

The usual automatic advance mechanism varies the ignition timing in accordance with the speed of the engine

through the use of centrifugal force caused by weights revolving with the ignition drive shaft. This is usually accomplished by fixing the pivot of the weight integral with one shaft and having another point on the weight connected to the other shaft by means of a pin and slot or by levers. The weights should be of such size that the amount of advance will not be affected by friction or vibration. The mechanism should be designed so that the resulting forces due to driving torque produce the least possible turning of the weights about their pivots, especially at slow speeds, when the centrifugal force is small and any forces due to friction or driving torque are comparatively large. However, the cost, accuracy, space available, and appearance must be considered in determining the design of the advance mechanism.

The desired rate of advance for most engines is approximately a direct function of the speed. It is usually convenient to design the pin and slot or link mechanism so that the angular movement of the weights will be nearly proportional to the spark advance. If such conditions exist, it is necessary that the weights move about their pivots through an angle that is practically pro-

Fig. 1—Diagram used in deducing the formula expressing relation between angular motion of pivoted weight used in advance mechanism and speed of driving shaft

portional to the speed. Since the centrifugal force on the rotating weights increases with the square of the speed and the tension of the spring only directly with its elongation, it becomes necessary to place the spring so that either its elongation or its moment arm increases rapidly as the weights swing outward. Since the centrifugal force of the weights is small at low speeds, the effect of the springs must be slight when the weights are in their initial position. This is usually accomplished by making the elongation on this position very small and by having the line of action of the springs pass nearly through the pivot of the weight, resulting in a small moment arm through which the spring may act.

A general case is illustrated in Fig. 1 and will be used in the following analysis. The method of analysis can be applied readily to practically any form of similar mechanism.

Let  $O$  be the shaft center;

$A$ , which is integral with the shaft, the pivot center of the weight;

Fig. 2—Examples of the pin and slot advance mechanism

$C$  the center of gravity of the weight;

$D$  the point where the spring is attached to the weight;

$E$  the point where the spring is attached to the fixed pin integral with the drive shaft.
